Chapter 1. Wicket Viewer

The Wicket Viewer automatically exposes an Apache Isis domain object model for use by end-users. The viewer is implemented using [Apache Wicket](#).

This user guide discuss end-user features, configuration and customization of the Wicket viewer.

It also discusses how to extend the viewer, and the (non-ASF) [Isis Addons](#) wicket components.

1.1. Other Guides

Apache Isis documentation is broken out into a number of user and reference guides.

The user guides available are:

- [Fundamentals](#)
- [Wicket viewer](#) (this guide)
- [Restful Objects viewer](#)
- [DataNucleus object store](#)
- [Security](#)
- [Testing](#)
- [Beyond the Basics](#)

The reference guides are:

- [Annotations](#)
- [Domain Services](#)
- [Configuration Properties](#)
- [Classes, Methods and Schema](#)
- [Apache Isis Maven plugin](#)
- [Framework Internal Services](#)

The remaining guides are:

- [Developers' Guide](#) (how to set up a development environment for Apache Isis and contribute back to the project)
- [Committers' Guide](#) (release procedures and related practices)

Chapter 2. Features/end-user usage

This section discusses features of the wicket viewer from the perspective of an end-user actually using your Isis application.

2.1. Recent pages (drop down)

The Wicket viewer provides a recent pages drop-down that acts as a breadcrumb trail. Using it, the user can quickly open a recently accessed domain object.

2.1.1. Screenshots

The following screenshot, taken from the [Estatio](#) application, shows the recent pages drop-down after a number of pages have been accessed.

The screenshot shows a web browser window for the 'ESTATIO' application at localhost:8080/wicket/entity/org.estatio.dom.lease.LeasedL_0. The main page displays a lease record for 'OXF-TOPMODEL-001'. On the right side, a modal dialog is open, showing a list of recently accessed objects. The list includes:

Object	Description
OXF-TOPMODEL-001	OXF-TOPMODEL-001: Rent
OXF-TOPMODEL-001	OXF-TOPMODEL-001: Rent: 15-07-2013--
TOPMODEL-Topmodel Fashion	TOPMODEL-Topmodel Fashion
OXF-TOPMODEL-001	Service Charge: 15-07-2012/14-07-2013

The modal also contains tabs for 'Items', 'Roles', 'Occupancies', 'Break Options', and 'Invoices', each with their own tables.

Note that this screenshot shows an earlier version of the [Wicket viewer](#) UI (specifically, pre 1.8.0).

2.1.2. Domain Code

The recent pages drop-down is automatically populated; no changes need to be made to the domain classes.

2.1.3. User Experience

Selecting the domain object from the list causes the viewer to automatically navigate to the page for the selected object.

2.1.4. Related functionality

The [bookmarked pages](#) (sliding panel) also provides links to recently visited objects, but only those explicitly marked as `@DomainObject(bookmarking=...)`. The bookmarks panel also nests related objects together hierarchically (the recent pages drop-down does not).

2.1.5. Configuration

The number of objects is hard-coded as 10; it cannot currently be configured.

2.2. Bookmarked pages

The Wicket viewer supports the bookmarking of both domain objects and query-only ([@Action\(semantics=...\)](#)) actions.

Domain objects, if bookmarkable, can be nested.

Bookmarking is automatic; whenever a bookmarkable object/action is visited, then a bookmark is created. To avoid the number of bookmarks from indefinitely growing, bookmarks that have not been followed after a while are automatically removed (an MRU/LRU algorithm). The number of bookmarks to preserve can be configured.

2.2.1. Screenshots

The following screenshot, taken from [Isisaddons example todoapp](#) (not ASF) shows how the bookmarks are listed in a sliding panel.

The screenshot shows a web browser window for the 'Not Yet Complete' application. The URL is localhost:8080/wicket/wicket/page?15. The top navigation bar includes links for 'CLEAR ALL', 'NOT YET COMPLETE', 'PROTOTYPING', 'ABOUT', and user 'SVEN'. A sliding panel on the left contains a list of bookmarked items under 'NOT YET COMPLETE': BUY BREAD DUE BY 2014-03-03, MOW LAWN DUE BY 2014-03-09, PICK UP LAUNDRY DUE BY 2014-03-09, SHARPEN KNIVES DUE BY 2014-03-17, STAGE ISIS RELEASE, BUY MILK, MOW LAWN, ORGANIZE BROWN BAG, PICK UP LAUNDRY, SHARPEN KNIVES, STAGE ISIS RELEASE, SUBMIT CONFERENCE SESSION, VACUUM HOUSE, and WRITE TO PENPAL. The main content area displays a table of tasks:

CATEGORY	SUBCATEGORY	COMPLETE	DU ^E BY	COST
DOMESTIC	SHOPPING	<input type="checkbox"/>	03-03-2014	1.75
DOMESTIC	SHOPPING	<input type="checkbox"/>	03-03-2014	0.75
DOMESTIC	GARDEN	<input type="checkbox"/>	09-03-2014	
PROFESSIONAL	CONSULTING	<input type="checkbox"/>	17-03-2014	
DOMESTIC	CHORES	<input type="checkbox"/>	09-03-2014	7.50
DOMESTIC	CHORES	<input type="checkbox"/>	17-03-2014	
PROFESSIONAL	OPENSOURCE	<input type="checkbox"/>		
PROFESSIONAL	EDUCATION	<input type="checkbox"/>	24-03-2014	
DOMESTIC	HOUSEWORK	<input type="checkbox"/>	06-03-2014	
OTHER	OTHER	<input type="checkbox"/>		

At the bottom of the page, there is a note 'POWERED BY APACHE ISIS' and a 'WICKET AJAX DEBUG' button.

Note that these screenshots show an earlier version of the [Wicket viewer](#) UI (specifically, pre 1.8.0).

Note how the list contains both domain objects and an action ("not yet complete").

Bookmarks can also form a hierarchy. The following screenshot, also taken from the [Estatio](#) application, shows a variety of different bookmarked objects with a nested structure:

The screenshot shows a Wicket-based application interface for managing lease terms. On the left, there's a sidebar with a tree view of bookmarks, including 'OXF-TOPMODEL-001' and 'OXF-TOPMODEL-001 RENT'. The main content area has tabs for 'MIGRATION', 'OTHER', and 'ADMINISTRATION'. The 'ADMINISTRATION' tab is active, showing a form for 'Indexable Rent' with fields like 'INDEX', 'STAT FOI', 'BASE INDEX START DATE', 'NEXT INDEX START DATE', 'EFFECTIVE DATE', and 'INDEXATION PERCENTAGE'. To the right of the form are sections for 'Values' (with fields for 'BASE VALUE', 'INDEXED VALUE', 'SETTLED VALUE', and a 'CHANGE VALUES' button) and 'Related' (with links to 'PREVIOUS TERM' and 'NEXT TERM'). At the bottom, there's a table titled 'Invoice Items (+)' showing a list of items with columns for 'INVOICE', 'CHARGE', 'QUANTITY', 'DESCRIPTION', 'DUE DATE', 'EFFECTIVE START DATE', 'EFFECTIVE END DATE', 'ADJUSTMENT', 'NET AMOUNT', and 'GROSS AMOUNT'. The table includes several rows for 'RENT' items. The footer of the page includes a 'POWERED BY: APACHE ISIS' link and a 'WICKET AJAX DEBUG' link.

Some - like [Property](#), [Lease](#) and [Party](#) - are root nodes. However, [LeaseItem](#) is bookmarkable as a child of [Lease](#), and [LeaseTerm](#) is bookmarkable only as a child of [LeaseItem](#). This parent/child relationship is reflected in the layout.

2.2.2. Domain Code

To indicate a class is bookmarkable, use the [@DomainObjectLayout](#) annotation:

```
@DomainObjectLayout(  
    bookmarking=BookmarkPolicy.AS_ROOT  
)  
public class Lease { ... }
```

To indicate a class is bookmarkable but only as a child of some parent bookmark, specify the bookmark policy:

```
@DomainObjectLayout(  
    bookmarking=BookmarkPolicy.AS_CHILD  
)  
public class LeaseItem { ... }
```

To indicate that a safe (query only) action is bookmarkable, use the `@ActionLayout` annotation:

```
public class ToDoItem ... {  
    @Action(  
        semantics=SemanticsOf.SAFE  
)  
    @ActionLayout(  
        bookmarking=BookmarkPolicy.AS_ROOT  
)  
    public List<ToDoItem> notYetComplete() { ... }  
    ...  
}
```

The `BookmarkPolicy.AS_CHILD` does not have a meaning for actions; if the `bookmarking` attribute is set to any other value, it will be ignored.

2.2.3. User Experience

The sliding panel appears whenever the mouse pointer hovers over the thin blue tab (to the left of the top header region).

Alternatively, `alt+[` will toggle open/close the panel; it can also be closed using `Esc` key.

Related functionality

The [Recent Pages](#) also lists recently visited pages, selected from a drop-down.

2.2.4. Configuration

By default, the bookmarked pages panel will show a maximum of 15 'root' pages. This can be overridden using a property (in `isis.properties`), for example:

```
isis.viewer.wicket.bookmarkedPages.maxSize=20
```

2.3. Hints and copy URL

While the user can often copy the URL of a domain object directly from the browser's address bar, the Wicket viewer also allows the URL of domain objects to be easily copied from a dialog.

More interestingly, this URL can also contain hints capturing any sorting or page numbering, or hiding/viewing of collections. End-users can therefore share these URLs as a form of deep linking

into a particular view on a domain object.

The copy URL and hinting is automatic.

2.3.1. Screenshots

The following screenshots are taken from the [Estatio](<https://github.com/estatio/estatio>) application.

Copy URL

This screenshot shows the copy URL button (top right):

The screenshot shows a web-based application interface for managing leases. At the top, there's a navigation bar with links for FIXED ASSETS, PARTIES, ACCOUNTS, LEASES, INVOICES, INDICES, MIGRATION, OTHER, and ADMINISTRATION. The main content area is titled 'ESTATIO' and shows a form for 'OXF-TOPMODEL-001'. The form includes sections for General (with fields like FIXED ASSET, REFERENCE, NAME, TYPE, LEASE TYPE, STATUS, PAID BY), Parties (with PRIMARY PARTY and SECONDARY PARTY), and Related (with PREVIOUS AGREEMENT and NEXT AGREEMENT). Below these are several tabs: Dates, Items (+), Roles (+), Occupancies (+), Break Options (+), and Invoices (+). The 'Items (+)' tab displays a table of charges:

TYPE	STATUS	CHARGE	START DATE	END DATE	VALUE
RENT	ACTIVE	RENT-RENT	15-07-2010	14-07-2022	21,305.02
TOURNOVER RENT	ACTIVE	TOURNOVER_RENT-TOURNOVER RENT	15-07-2010	14-07-2022	0.00
SERVICE CHARGE	ACTIVE	SERVICE_CHARGE-SERVICE CHARGE	15-07-2010	14-07-2022	6,000.00

The 'Roles (+)' tab shows a table of roles:

TYPE	PARTY	START DATE	END DATE
LANDLORD	ACME-ACME PROPERTIES INTERNATIONAL		
MANAGER	JDOE-DOE, JOHN		
TENANT	TOPMODEL-TOPMODEL FASHION		

The 'Occupancies (+)' tab shows a table of occupancies:

UNIT	START DATE	END DATE	SECTOR	ACTIVITY	BRAND	UNIT SIZE
OXF-001 UNIT 1	15-07-2010		FASHION	FASHIONWOMEN	TOPMODEL	

The 'Break Options (+)' tab shows a table of break options:

TYPE	EXERCISE TYPE	BREAK DATE	EXERCISE DATE	NOTIFICATION PERIOD
FIXED	MUTUAL	15-07-2015	15-01-2015	6M
ROLLING	MUTUAL	15-07-2022	15-01-2022	6M

The 'Invoices (+)' tab has a 'NEW ITEM' button. At the bottom right of the page, there are links for 'WICKET AJAX DEBUG' and 'POWERED BY: APACHE ISIS'.

Note that these screenshots show an earlier version of the [Wicket viewer](#) UI (specifically, pre 1.8.0).

Clicking on this button brings up a dialog with the URL preselected:

The screenshot shows the OXF-TOPMODEL-001 application's lease management screen. A modal dialog box is centered over the 'Items (+)' collection table. The dialog contains the text 'COPY THIS URL:' followed by the URL 'http://localhost:8080/wicket/entity/org.estatio.dom.lease.Lease:0'. At the bottom of the dialog is an 'OK' button.

The URL in this case is something like:

`http://localhost:8080/wicket/entity/org.estatio.dom.lease.Lease:0`

The user can copy the link (eg **ctrl+C**) into the clipboard, then hit **OK** or **Esc** to dismiss the dialog.

Hints

Using the viewer the user can hide/show collection tables, can sort the tables by header columns:

The screenshot shows the same lease record as the previous one, but with a different state. The 'Items (+)' collection table is now collapsed, indicated by a minus sign icon. Instead, the 'Invoices (5)' collection table is expanded, showing five items. The other collection tables ('Occupancies', 'Break Options') remain visible.

Also, if the collection spans multiple pages, then the individual page can be selected.

Once the view has been customised, the URL shown in the copy URL dialog is in an extended form:

The screenshot shows the ESTATIO application interface for managing leases. On the left, there's a sidebar with sections like General, Parties, and Related. The main area displays a lease record for 'OXF-TOPMODEL-001' with fields for Fixed Asset Set, Reference, Name, Type, Lease Type, Status, Paid By, and Parties (Primary and Secondary). A modal dialog is open in the center, prompting the user to 'COPY THIS URL:' with the value <http://localhost:8080/wicket/entity/org.estatio.dom.lease.Lease:0?hint-1:collectionContents-view=3&hint-1:collectionContents:collectionContents-3:table-DESCENDING=value&hint-1:collectionContents:collectionContents-3:table-pageNumber=0&hint-2:collectionContents-view=0&hint-2:collectionContents:collectionContents-2:table-pageNumber=0&hint-3:collectionContents-view=2&hint-3:collectionContents:collectionContents-2:table-pageNumber=0&hint-4:collectionContents-view=3&hint-4:collectionContents:collectionContents-3:table-ASCENDING=exerciseDate&hint-4:collectionContents:collectionContents-3:table-pageNumber=0&hint-5:collectionContents-view=0&hint-5:collectionContents:collectionContents-3:table-pageNumber=0>. Below the modal, there are tabs for Dates, Items (+), Break Options (+), and Invoices (5).

The URL in this case is something like:

```
http://localhost:8080/wicket/entity/org.estatio.dom.lease.Lease:0?hint-1:collectionContents-view=3&hint-1:collectionContents:collectionContents-3:table-DESCENDING=value&hint-1:collectionContents:collectionContents-3:table-pageNumber=0&hint-2:collectionContents-view=0&hint-2:collectionContents:collectionContents-2:table-pageNumber=0&hint-3:collectionContents-view=2&hint-3:collectionContents:collectionContents-2:table-pageNumber=0&hint-4:collectionContents-view=3&hint-4:collectionContents:collectionContents-3:table-ASCENDING=exerciseDate&hint-4:collectionContents:collectionContents-3:table-pageNumber=0&hint-5:collectionContents-view=0&hint-5:collectionContents:collectionContents-3:table-pageNumber=0
```

Copy URL from title

When the user invokes an action on the object, the URL (necessarily) changes to indicate that the action was invoked. This URL is specific to the user's session and cannot be shared with others.

A quick way for the user to grab a shareable URL is simply by clicking on the object's title:

Buy bread due by 2014-03-03

WICKET AJAX DEBUG

2.3.2. User Experience

The copy URL dialog is typically obtained by clicking on the icon.

Alternatively, **alt+J** will also open the dialog. It can be closed with either **OK** or the **Esc** key.

2.4. Titles in Tables

Object titles can often be quite long if the intention is to uniquely identify the object. While this is appropriate for the object view, it can be cumbersome within tables.

If an object's title is specified with from **@Title** annotation then the Wicket viewer will (for parented collections) automatically "contextualize" a title by excluding the part of the title corresponding to a reference to the owning (parent) object.

In other words, suppose we have:

so that **Customer** has a collection of `Order`'s:

```
public class Customer {
    public Set<Order> getOrders() { ... }
    ...
}
```

and **Product** also has a collection of `Order`'s (please forgive the suspect domain modelling in this example (!)):

```
public class Product {
    public Set<Order> getOrders() { ... }
    ...
}
```

and where the **Order** class references both **Customer** and **Product**.

The `Order's might involve each of these:

```
public class Order {
    @Title(sequence="1")
    public Customer getCustomer() { ... }
    @Title(sequence="2")
    public Product getProduct() { ... }
    @Title(sequence="3")
    public String getOtherInfo() { ... }
    ...
}
```

In this case, if we view a **Customer** with its collection of **Order**'s, then in that parented collection's table the **customer**'s property will be automatically excluded from the title of the 'Order' (but it would show the product). Conversely, if a **Product** is viewed then its collection of `Order`'s would suppress product (but would show the customer).

This feature is a close cousin of the **@PropertyLayout(hidden=Where.REFERENCES_PARENT)** annotation, which will cause the property itself to be hidden as a column in the table. An Isis idiom is therefore:

```
public class Order {
    @Title(sequence="1")
    @PropertyLayout(hidden=Where.REFERENCES_PARENT)
    public Customer getCustomer() { ... }
    ...
}
```

The above annotations mean that titles usually "just work", altering according to the context in

which they are viewed.

It is also possible to configure the Wicket viewer to [abbreviate titles](#) or [suppress them](#) completely.

2.5. File upload/download

The Isis application library provides the [Blob](#) value type (binary large objects) and also the [Clob](#) value type (character large object), each of which also includes metadata about the data (specifically the filename and mime type).

A class can define a property using either of these types, for example:

2.5.1. Screenshots

The following screenshots are taken from the Isis addons example [todoapp](#) (not ASF):

View mode, empty

[Blob](#) field rendered as attachment (with no data):

The screenshot shows a web browser window for the 'Buy bread due by 2014-03-02' record. The page has a dark header with 'APACHE ISIS' and navigation links like 'TODOS', 'ANALYSIS', 'ADMIN', and 'PROTOTYPING'. The main content area shows the record details in two columns. The left column contains fields for 'DESCRIPTION' (Buy bread), 'CATEGORY' (Domestic), 'SUBCATEGORY' (Shopping), and 'COMPLETE' status. The right column contains 'Priority' (relative priority 1, due by 02-03-2014), 'Other' (cost 1.75), and 'NOTES'. A large 'ATTACHMENT' field is present, which is highlighted with a red rectangle. Below the main form, there are sections for 'Dependencies' and 'Similar To', both currently empty. At the bottom, there's a footer with 'POWERED BY: APACHE ISIS' and a 'WICKET AJAX DEBUG' link.

Note that these screenshots show an earlier version of the [Wicket viewer](#) UI (specifically, pre 1.8.0).

Edit mode

Hit edit; 'choose file' button appears:

The screenshot shows a task creation form for 'Buy bread due by 2014-03-02'. The 'ATTACHMENT' field, which contains the placeholder 'Choose File No file chosen', is highlighted with a red box.

Choose file

Choose file using the regular browser window:

Download

Blob can be downloaded:

The screenshot shows the Apache ISIS application interface. At the top, there's a navigation bar with links for Todos, Analysis, Admin, and Prototyping. On the right, there are links for SVN, Logout, and About. The main content area is titled 'Buy bread due by 2014-03-02'. It has several sections: General (Description: Buy bread, Category: Domestic, Subcategory: Shopping), Priority (Relative Priority: 1, Due By: 02-03-2014), Other (Cost: 1.75), and Misc (Version: 2). Below these are sections for Dependencies and Similar To. A red box highlights the 'CLEAR' button next to the attachment input field.

Clear

Back in edit mode, can choose a different file or clear (assuming property is not mandatory):

This screenshot shows the same task 'Buy bread due by 2014-03-02' in edit mode. The attachment section now displays a file input field containing 'image.jpg' and a red box highlights the 'CLEAR' button. The rest of the interface is identical to the previous screenshot.

2.5.2. Domain Code

To define a **Blob**, use:

```

private Blob attachment;
@javax.jdo.annotations.Persistent(defaultFetchGroup="false")
    @javax.jdo.annotations.Persistent(defaultFetchGroup="false", columns = {
        @javax.jdo.annotations.Column(name = "attachment_name"),
        @javax.jdo.annotations.Column(name = "attachment_mimetype"),
        @javax.jdo.annotations.Column(name = "attachment_bytes", jdbcType = "BLOB"
", sqlType = "BLOB")
    })
@Property(
    domainEvent = AttachmentDomainEvent.class,
    optionality = Optionality.OPTIONAL
)
public Blob getAttachment() { return attachment; }
public void setAttachment(final Blob attachment) { this.attachment = attachment; }

```

To define a **Clob**, use:

```

private Clob doc;
@javax.jdo.annotations.Persistent(defaultFetchGroup="false", columns = {
    @javax.jdo.annotations.Column(name = "doc_name"),
    @javax.jdo.annotations.Column(name = "doc_mimetype"),
    @javax.jdo.annotations.Column(name = "doc_chars", jdbcType = "CLOB", sqlType =
"CLOB")
})
@Property(
    optionality = Optionality.OPTIONAL
)
public Clob getDoc() { return doc; }
public void setDoc(final Clob doc) { this.doc = doc; }

```

The **Blob** and **Clob** types can also be used as parameters to actions.

2.6. User Registration

The Wicket viewer provides the ability for users to sign-up by providing a valid email address:

- from the login page the user can instead follow a link to take them to a sign-up page, where they enter their email address.
- a verification email is sent using this service; the email includes a link back to the running application.
- the user then completes the registration process by choosing a user name and password.
- the Wicket viewer then creates an account for them and logs them in.

In a similar way, if the user has forgotten their password then they can request a reset link to be sent to their email, again by providing their email address.

To support this the framework requires three services to be registered and configured:

- the [user registration service](#), which provides an API to create the user account
- the [email notification service](#), which provides an API for to send the verification emails
- the [email service](#), that is used by the email notification service to actually send the email.

The Apache Isis core framework provides a default implementation of both the email notification service and the email service. If your application uses the [Isis addons security module](#) (not ASF) then an implementation is provided by that module; just add to the classpath. Otherwise you will need to provide your own implementation.

There is *no* default implementation of the user registration service in the core framework.

2.6.2. Configuration

There are two prerequisites:

- register an implementation of the [user registration service](#) (eg by using the [Isis addons security module](#))
- configure the [email service](#)

The latter is required if you are using the default email notification service and email service. If you are using your own alternative implementation of the email notification service then it may be omitted (and configure your own alternative implementation as required).

It is also possible to configure the Wicket viewer to suppress [the sign-up page link](#) and/or the [password reset page](#).

Chapter 3. Layout

In implementing the [naked objects pattern](#), Apache Isis aims to infer as much information from the domain classes as possible. Nevertheless, some metadata relating solely to the UI is inevitably required. This chapter describes how this is done both for domain objects using either annotations or using an associated layout file.

It also describes how to layout the application menu items (containing domain service' actions), as more well as more advanced topics such as customising which columns appear in tables.

3.1. Annotation-based Layout

Metadata providing UI hints can be specified either using annotations, or using a `layout.xml` file.

In most cases you will probably want to use the file-based approach: changes to file layouts are picked up dynamically, and using a file also allows tabs and tab groups to be specified: this is not supported using annotations.

Nevertheless, annotations are still supported and are sometimes useful for very simple objects or just when prototyping. This section explains how.

3.1.1. @MemberOrder

The `@MemberOrder` annotation is used to specify the relative order of domain class properties, collections and actions.

The annotation defines two attributes, `name()` and `sequence()`. Their usage depends on the member type:

- for properties, the `name()` is used to group properties together into a member group (also called a property group or a fieldset. The `sequence()` then orders properties within these groups. If no `name()` is specified then the property is placed in a fallback "General" group, called "General".

The name of these member groups/fieldset are then referenced by `@MemberGroupLayout`.

- for collections, the `name()` attribute is (currently) unused. The `sequence()` orders collections relative to one another
- for actions, the `name()` attribute associates an action with either a property or with a collection.
 - If the `name()` attribute matches a property name, then the action's button is rendered close to the property, according to `@ActionLayout#position()` attribute.
 - On the other hand if the `name() attribute matches a collection name, then the action's button is rendered on the collection's header.
 - If there is no `name()` value, then the action is considered to pertain to the object as a whole, and its button is rendered close to the object's icon and title.

Within any of these, the `sequence()` then determines the relative ordering of the action with respect to other actions that have been similarly associated with properties/collections or left as "free-

standing".

For example:

```
public class ToDoItem {  
    @MemberOrder(sequence="1")  
    public String getDescription() { ... }  
    @MemberOrder(sequence="2")  
    public String getCategory() { ... }  
    @MemberOrder(sequence="3")  
    public boolean isComplete() { ... }  
    @MemberOrder(name="Detail", sequence="1")  
    public LocalDate getDueBy() { ... }  
    @MemberOrder(name="Detail", sequence="2")  
    public BigDecimal getCost() { ... }  
    @MemberOrder(name="Detail", sequence="4")  
    public String getNotes() { ... }  
    @MemberOrder(name="Misc", sequence="99")  
    public Long getVersionSequence() { ... }  
    ...  
}
```

This defines three property (or member) groups, "General", "Detail" and "Misc"; "General" is the default if no `name` attribute is specified. Properties in the same member group are rendered together, as afieldset.

In addition, actions can optionally be associated (rendered close to) either properties or actions. This is done by overloading the `@MemberOrder`'s `name()` attribute, holding the value of the property or collection.

For example:

```
public class ToDoItem {  
    @MemberOrder(sequence="3")  
    public boolean isComplete() { ... }  
    @MemberOrder(name="complete", sequence="1")  
    public ToDoItem completed() { ... }  
    @MemberOrder(name="complete", sequence="2")  
    public ToDoItem notYetCompleted() { ... }  
  
    @MemberOrder(sequence="1")  
    public SortedSet<ToDoItem> getDependencies() { ... }  
    @MemberOrder(name="dependencies", sequence="1")  
    public ToDoItem add(ToDoItem t) { ... }  
    @MemberOrder(name="dependencies", sequence="2")  
    public ToDoItem remove(ToDoItem t) { ... }  
    ...  
}
```

will associate the `completed()` and `notYetCompleted()` actions with the `complete` property, and will associate the `add()` and `remove()` actions with the `dependencies` collection.

The value of `sequence()` is a string. The simplest convention (as shown in the example above) is to use numbers—1, 2, 3—though it is a better idea to leave gaps in the numbers—10, 20, 30 perhaps—such that a new member may be added without having to edit existing numbers.

Even better is to adopt the 'dewey-decimal' notation—1, 1.1, 1.2, 2, 3, 5.1.1, 5.2.2, 5.2, 5.3—which allows for an indefinite amount of future insertion. It also allows subclasses to insert their class members as required.

3.1.2. @MemberGroupLayout

The `@MemberGroupLayout` annotation specifies the relative positioning of property groups/fieldsets as being either in a left column, a middle column or in a right column. The annotation also specifies the relative width of the columns.

The property groups/fieldsets in this case are those that are inferred from the `@MemberOrder#name()` attribute.

It is also possible to combine `@MemberOrder` with a [file-based layout](#). The layout file defines only the regions of a grid structure (fieldsets/columns etc), but does *not* specify the properties/collections/actions within those grid regions. The `@MemberOrder` annotation in effect "binds" the properties or collections to those regions of the grid.

When file-based layouts are used this way, the `@MemberGroupLayout` annotation is essentially ignored, but the metadata from the `@MemberOrder` annotation (and the other layout annotations, `@ActionLayout`, `@PropertyLayout` and `@CollectionLayout`) are all still honoured.

For example:

```
@MemberGroupLayout(
    columnSpans={3,3,0,6},
    left={"General", "Misc"},
    middle="Detail"
)
public class ToDoItem {
    ...
}
```

Four values are given in the `columnSpans` attribute. The first three are the relative widths of the three columns of property groups. The fourth, meanwhile, indicates the width of a final column that holds all the collections of the object.

The values of these spans are taken as proportions of 12 virtual columns across the page (this taken from the [Bootstrap](#) library).

For example:

- **{3,3,0,6}** indicates:
 - a left column of properties taking up 25% of the width
 - a middle column of properties taking up 25% of the width
 - a right column of collections taking up 50% of the width
- **{2,6,0,4}** indicates:
 - a left column of properties taking up ~16% of the width
 - a middle column of properties taking up 50% of the width
 - a right column of collections taking up ~33% of the width
- **{2,3,3,4}** indicates:
 - a left column of properties taking up ~16% of the width
 - a middle column of properties taking up 25% of the width
 - a right column of properties taking up 25% of the width
 - a far right column of collections taking up ~33% of the width

If the sum of all the columns exceeds 12, then the collections are placed underneath the properties, taking up the full span. For example:

- **{4,4,4,12}** indicates:
 - a left column of properties taking up ~33% of the width
 - a middle column of properties taking up ~33% of the width
 - a right column of properties taking up ~33% of the width
 - the collections underneath the property columns, taking up the full width

3.1.3. Example Layouts

Below are sketches for the layout of the `ToDoItem` class of the Isis addons example `todoapp` (not ASF):

The first divides the properties into two equal sized columns (6-6-0) and puts the collections underneath (12):

colspans={6,6,0,12}

Buy bread		delete	clone	recentChanges	recentChanges
General					
<div><p>description</p><p>category</p><p>subcategory</p><p>update analyseCategory</p><p>done</p><p>done scheduleExplicitly scheduleImplicitly not done</p></div>					
Priority					
<div><p>relativePriority</p><p>previous next</p><p>dueBy</p></div>					
Other					
<div><p>cost</p><p>update</p><p>notes</p><p>attachment</p></div>					
Misc					
<div><p>version</p></div>					
dependencies					
<div><p>add remove</p></div>					
similarTo					

The next divides the collections into three equal sized columns (4-4-4) and again puts the collections underneath (12):

colspans={4,4,4,12}

Buy bread										
delete clone recentChanges recentChanges										
General										
<table border="1"><tr><td>description</td></tr><tr><td>category</td></tr><tr><td>subcategory</td></tr><tr><td>update analyseCategory</td></tr><tr><td>done</td></tr><tr><td>done scheduleExplicitly</td></tr><tr><td>scheduleImplicitly not done</td></tr></table>				description	category	subcategory	update analyseCategory	done	done scheduleExplicitly	scheduleImplicitly not done
description										
category										
subcategory										
update analyseCategory										
done										
done scheduleExplicitly										
scheduleImplicitly not done										
Priority										
<table border="1"><tr><td>relativePriority</td></tr><tr><td>previous next</td></tr><tr><td>dueBy</td></tr></table>				relativePriority	previous next	dueBy				
relativePriority										
previous next										
dueBy										
Other										
<table border="1"><tr><td>cost</td></tr><tr><td>update</td></tr><tr><td>notes</td></tr><tr><td>attachment</td></tr></table>				cost	update	notes	attachment			
cost										
update										
notes										
attachment										
Misc										
<table border="1"><tr><td>version</td></tr></table>				version						
version										
dependencies										
<table border="1"><tr><td>add remove</td></tr></table>				add remove						
add remove										
similarTo										
<table border="1"><tr><td> </td></tr></table>										

The last puts the properties into a single column (4-0) and places the collections into the other larger column (8-0):

colspans={4,0,8,0}

The screenshot shows a UI interface for managing a bread item. At the top, there's a green header bar with the title "Buy bread". To the right of the title are four buttons: "delete", "clone", "recentChanges", and "recentChanges". Below the header, the interface is divided into several sections:

- General**: Contains fields for "description", "category", "subcategory", and buttons for "update", "analyseCategory", "done", "done", "scheduleExplicitly", "scheduleImplicitly", and "not done".
- dependencies**: Contains a "similarTo" field and buttons for "add" and "remove".
- Priority**: Contains fields for "relativePriority", "previous", "next", and "dueBy".
- Other**: Contains fields for "cost", "update", "notes", "attachment", and "version".

3.1.4. Other Annotations

As of 1.8.0, all the layout annotations have been consolidated into the various `XxxLayout` annotations: `@ActionLayout`, `@CollectionLayout`, `@DomainObjectLayout`, `@DomainServiceLayout`, `@ParameterLayout`, `@PropertyLayout`, and `@ViewModellLayout`

3.2. File-based Layouts

Metadata providing UI hints can be specified either [using annotations](#), or using an `Xxx.layout.xml` file (where `Xxx` is the entity or view model object to be rendered).

Using a file-based layout has the huge benefit that the layout can be updated without requiring a recompile of the code and redeploy of the app. Many developers also find it easier to rationalize about layout when all the hints are collated together in a single place (rather than scattered across the class members as annotations).

Another benefit of file-based layout is that UI hints can be provided for [contributed associations](#) and [actions](#) that are synthesised at runtime.

It is also possible to download an initial `.layout.xml` - capturing any existing layout metadata - using the `LayoutService` (exposed on the prototyping menu) or using a [mixin action](#) contributed to every

domain object.

The main downsides of using file-based layouts are a lack of typesafety (a typo will result in the metadata not being picked up for the element) and syntactic fragility (an invalid XML document will result in no metadata for the entire class).

Also, file-based layouts have no notion of inheritance, whereas the dewey-decimal format `@MemberOrder` annotation allows the metadata of the subclass its superclasses to fit together relatively seamlessly.

The `Xxx.layout.xml` file is just the serialized form of a `Grid` layout class defined within Apache Isis' applib. These are JAXB-annotated classes with corresponding XSD schemas; the upshot of that is that IDEs such as IntelliJ and Eclipse can provide "intellisense", making it easy to author such layout files.

It is also possible to describe layouts using a `.layout.json` file. However, `.layout.json` support is deprecated; the `.layout.xml` file also enables much more sophisticated layouts than those afforded by `.layout.json`.

If you have an application with older `.layout.json` files, then it is possible to download initial `.layout.xml` files using the `LayoutService` (exposed as an action on the prototyping menu). The `.layout.json` file will be ignored once a `.layout.xml` file is present.

3.2.1. Grids vs Components

The layout file distinguishes between two types of element:

- those that define a grid structure, of: rows, columns, tab groups and tabs.

The rows and columns are closely modelled on [Bootstrap 3](#) (used in the implementation of the [Wicket viewer](#)).

- those that defines common components, of: fieldsets (previously called member groups or property groups), properties, collections, actions and also the title/icon of the domain object itself.

More information about these classes can be found in [the reference guide](#). More information on Bootstrap 3's grid system can be found [here](#).

3.2.2. Screencast

This [screencast](#) describes the feature.

3.2.3. Examples

Probably the easiest way to understand dynamic XML layouts is by example. For this we'll use the `ToDoItem` from the (non-ASF) [Isis addons' todoapp](#):

Namespaces

First things first; every `.layout.xml` file must properly declare the XSD namespaces and schemas. There are two: one for the grid classes, and one for the common component classes:

```

<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<bs3:grid
    xsi:schemaLocation="http://isis.apache.org/applib/layout/component
                        http://isis.apache.org/applib/layout/component/component.xsd
                        http://isis.apache.org/applib/layout/grid/bootstrap3

    http://isis.apache.org/applib/layout/grid/bootstrap3/bootstrap3.xsd"
    xmlns:bs3="http://isis.apache.org/applib/layout/grid/bootstrap3"
    xmlns:c="http://isis.apache.org/applib/layout/component"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
    ...
</bs3:grid>
```

Most IDEs will automatically download the XSD schemas from the specified schema locations, thereby providing "intellisense" help as you edit the file.

Rows, full-width cols, and tabs

The example layout consists of three rows: a row for the object/icon, a row containing a properties, and a row containing collections. In all three cases the row contains a single column spanning the full width of the page. For the property and collection rows, the column contains a tab group.

This corresponds to the following XML:

```
<bs3:row>
    <bs3:col span="12" unreferencedActions="true">
        <c:domainObject bookmarking="AS_ROOT"/>
    </bs3:col>
</bs3:row>
<bs3:row>
    <bs3:col span="12">
        <bs3:tabGroup>
            <bs3:tab name="Properties">...</bs3:tab>
            <bs3:tab name="Other">...</bs3:tab>
            <bs3:tab name="Metadata">...</bs3:tab>
        </bs3:tabGroup>
    </bs3:col>
</bs3:row>
<bs3:row>
    <bs3:col span="12">
        <bs3:tabGroup unreferencedCollections="true">
            <bs3:tab name="Similar to">...</bs3:tab>
            <bs3:tab name="Dependencies">...</bs3:tab>
        </bs3:tabGroup>
    </bs3:col>
</bs3:row>
```

You will notice that one of the `columns` has an `unreferencedActions` attribute, while one of the `tabGroups` has a similar `unreferencedCollections` attribute. This topic is discussed in more detail [below](#).

Fieldsets

The first tab containing properties is divided into two columns, each of which holds a single fieldset of multiple properties. Those properties in turn can have associated actions.

This corresponds to the following XML:

```

<bs3:tab name="Properties">
    <bs3:row>
        <bs3:col span="6">
            <c:fieldSet name="General" id="general"
unreferencedProperties="true">
                <c:action id="duplicate" position="PANEL_DROPDOWN"/>
                <c:action id="delete"/>
                <c:property id="description"/>
                <c:property id="category"/>
                <c:property id="subcategory">
                    <c:action id="updateCategory"/>
                    <c:action id="analyseCategory" position="RIGHT"/>
                </c:property>
                <c:property id="complete">
                    <c:action id="completed" cssClassFa="fa-thumbs-up"/>
                    <c:action id="notYetCompleted" cssClassFa="fa-thumbs-
down"/>
                </c:property>
            </c:fieldSet>
        </bs3:col>
        <bs3:col span="6">
            ...
        </bs3:col>
    </bs3:row>
</bs3:tab>

```

The tab defines two columns, each span of 6 (meaning half the width of the page).

In the first column there is a single fieldset. Notice how actions - such as `duplicate` and `delete` - can be associated with this fieldset directly, meaning that they should be rendered on the fieldset's top panel.

Thereafter the fieldset lists the properties in order. Actions can be associated with properties too; here they are rendered underneath or to the right of the field.

Note also the `unreferencedProperties` attribute for the fieldset; this topic is discussed in more detail [below](#).

Collections

In the final row the collections are placed in tabs, simply one collection per tab. This corresponds to the following XML:

```

<bs3:tab name="Similar to">
  <bs3:row>
    <bs3:col span="12">
      <c:collection defaultView="table" id="similarTo"/>
    </bs3:col>
  </bs3:row>
</bs3:tab>
<bs3:tab name="Dependencies">
  <bs3:row>
    <bs3:col span="12">
      <c:collection defaultView="table" id="dependencies">
        <c:action id="add"/>
        <c:action id="remove"/>
      </c:collection>
    </bs3:col>
  </bs3:row>
</bs3:tab>

```

As with properties, actions can be associated with collections; this indicates that they should be rendered in the collection's header.

3.2.4. Unreferenced Members

As noted in the preceding discussion, several of the grid's regions have either an `unreferencedActions`, `unreferencedCollections` or `unreferencedProperties` attribute.

The rules are:

- `unreferencedActions` attribute can be specified either on a column or on a fieldset.

It would normally be typical to use the column holding the `<domainObject/>` icon/title, that is as shown in the example. The unreferenced actions then appear as top-level actions for the domain object.

- `unreferencedCollections` attribute can be specified either on a column or on a tabgroup.

If specified on a column, then that column will contain each of the unreferenced collections, stacked one on top of the other. If specified on a tab group, then a separate tab will be created for each collection, with that tab containing only that single collection.

- `unreferencedProperties` attribute can be specified only on a fieldset.

The purpose of these attributes is to indicate where in the layout any unreferenced members should be rendered. Every grid *must* nominate one region for each of these three member types, the reason being that to ensure that the layout can be used even if it is incomplete with respect to the object members inferred from the Java source code. This might be because the developer forgot to update the layout, or it might be because of a new mixin (property, collection or action) contributed to many objects.

The framework ensures that in any given grid exactly one region is specified for each of the three

unreferenced... attributes. If the grid fails this validation, then a warning message will be displayed, and the invalid XML logged. The layout XML will then be ignored.

3.2.5. More advanced features

This section describes a number of more features useful in more complex layouts.

Multiple references to a feature

One feature worth being aware of is that it is possible to render a single feature more than once.

For example, the dashboard home page for the (non-ASF) [Isis addons' todoapp](#) shows the "not yet complete" collection of todo items twice, once as a table and also as a calendar:

The screenshot shows a web-based application interface for a 'ToDo App'. On the left, there's a sidebar with buttons for 'Export To Word Doc', 'Export As Xml', 'Download Layout Xml', and 'Rebuild Metamodel'. The main area has a title 'Dashboard' with a clock icon. Below it is a 'Not Yet Complete' section containing a 'Calendar' view for March 2016. The calendar highlights several dates with green boxes, each containing a list of pending tasks. To the right of the calendar are two tables: one titled 'Not Yet Complete' and another titled 'Complete'. Both tables have columns for Description, Category, Subcategory, Complete status, Due By date, and Cost. The 'Not Yet Complete' table shows five items, while the 'Complete' table shows two items.

Description	Category	Subcategory	Complete	Due By	Cost
Buy bread	Domestic	Shopping	<input type="checkbox"/>	16-03-2016	1.75
Buy milk	Domestic	Shopping	<input type="checkbox"/>	16-03-2016	0.75
Buy stamps	Domestic	Shopping	<input type="checkbox"/>	16-03-2016	10.00
Vacuum house	Domestic	Housework	<input type="checkbox"/>	19-03-2016	
Mow lawn	Domestic	Garden	<input type="checkbox"/>	22-03-2016	

Description	Category	Subcategory	Complete	Due By	Cost
Organize brown bag	Professional	Consulting	<input checked="" type="checkbox"/>	30-03-2016	
Submit conference session	Professional	Education	<input checked="" type="checkbox"/>	06-04-2016	

This is accomplished using the following (slightly abbreviated) layout:

```

<grid ...>
  <row>
    <col span="2" unreferencedActions="true">
      ...
    </col>
    <col span="5" unreferencedCollections="true" cssClass="custom-padding-top-20">
      <ns2:collection id="notYetComplete" defaultView="calendar"/>
①
      </col>
      <col span="5" cssClass="custom-padding-top-20">
        <ns2:collection id="notYetComplete" defaultView="table" paged="5"/>
②
        <ns2:collection id="complete" defaultView="table"/>
      </col>
      <col span="0">
        <ns2:fieldSet name="General" id="general" unreferencedProperties="true"/>
      </col>
    </row>
  </grid>

```

① render the collection in "calendar" view

② also render the collection in "table" view

In the middle column the `notYetComplete` collection is rendered in "calendar" view, while in the right-most column it is rendered in "table" view.

It is also possible to reference object properties and actions more than once. This might be useful for a complex domain object with multiple tabs; certain properties or actions might appear on a summary tab (that shows the most commonly used info), but also on detail tabs.

Custom CSS

The ToDoApp's dashboard (above) also shows how custom CSS styles can be associated with specific regions of the layout:

```

<grid ...>
  <row>
    <col span="2" unreferencedActions="true">
      <ns2:domainObject/>
      <row>
        <col span="12" cssClass="custom-width-100">
          ①
            <ns2:action id="exportToWordDoc"/>
          </col>
        </row>
        ...
        </col>
      <col span="5" unreferencedCollections="true" cssClass="custom-padding-top-20">
        ②
        ...
        </col>
      <col span="5" cssClass="custom-padding-top-20">
        ③
        ...
        </col>
      </row>
    </grid>

```

- ① Render the column with the `custom-width-100` CSS class.
- ② Render the column with the `custom-padding-top-20` CSS class.
- ③ Ditto

For example the `custom-width-100` style is used to "stretch" the button for the `exportToWordDoc` action in the left-most column. This is accomplished with the following CSS in `application.css`:

```

.custom-width-100 ul,
.custom-width-100 ul li,
.custom-width-100 ul li a.btn {
  width: 100%;
}

```

Similarly, the middle and right columns are rendered using the `custom-padding-top-20` CSS class. This shifts them down from the top of the page slightly, using the following CSS:

```

.custom-padding-top-20 {
  padding-top: 20px;
}

```

3.2.6. Migrating from earlier versions

As noted earlier on, it is possible to download layout XML files using the `LayoutService` (exposed on

the prototyping menu); this will download a ZIP file of layout XML files for all domain entities and view models. Alternatively the layout XML for a single domain object can be downloaded using the [mixin action](#) (contributed to every domain object).

There are four "styles":

- current
- complete
- normalized
- minimal

Ignoring the "current" style (which merely downloads the currently cached layout), the other three styles allow the developer to choose how much metadata is to be specified in the XML, and how much (if any) will be obtained elsewhere, either from annotations in the metamodel or from an earlier `.layout.json` file if present. The table below summarises the choices:

Table 1. Table caption

Style	<code>@MemberGroupLayout</code>	<code>@MemberOrder</code>	<code>@ActionLayout</code> , <code>@PropertyLayout</code> , <code>@CollectionLayout</code>
<code>COMPLETE</code>	serialized as XML	serialized as XML	serialized as XML
<code>NORMALIZED</code>	serialized as XML	serialized as XML	not in the XML
<code>MINIMAL</code>	serialized as XML	not in the XML	not in the XML

As a developer, you therefore have a choice as to how you provide the metadata required for customised layouts:

- if you want all layout metadata to be read from the `.layout.xml` file, then download the "complete" version, and copy the file alongside the domain class. You can then remove all `@MemberGroupLayout`, `@MemberOrder`, `@ActionLayout`, `@PropertyLayout` and `@CollectionLayout` annotations from the source code of the domain class.
- if you want to use layout XML file to describe the grid (columns, tabs etc) and specify which object members are associated with those regions of the grid, then download the "normalized" version. You can then remove the `@MemberGroupLayout` and `@MemberOrder` annotations from the source code of the domain class, but retain the `@ActionLayout`, `@PropertyLayout` and `@CollectionLayout` annotations.
- if you want to use layout XML file ONLY to describe the grid, then download the "minimal" version. The grid regions will be empty in this version, and the framework will use the `@MemberOrder` annotation to bind object members to those regions. The only annotation that can be safely removed from the source code with this style is the `@MemberGroupLayout` annotation.

Download either for a single domain object, or download all domain objects (entities and view models).

3.2.7. Domain Services

For more information about layouts, see:

- [LayoutService](#) (whose functionality is exposed on the prototyping menu as an action) and also the [Mixin action](#)
- [GridService](#) and its supporting services, [GridLoaderService](#) and [GridSystemService](#)
- [grid layout classes](#), defined in the Apache Isis applib

3.2.8. Required updates to the dom project's pom.xml

Any [.layout.xml](#) files must be compiled and available in the classpath. Ensure the following is defined in the dom project's [pom.xml](#):

```
<resources>
  <resource>
    <filtering>false</filtering>
    <directory>src/main/resources</directory>
  </resource>
  <resource>
    <filtering>false</filtering>
    <directory>src/main/java</directory>
    <includes>
      <include>**</include>
    </includes>
    <excludes>
      <exclude>**/*.java</exclude>
    </excludes>
  </resource>
</resources>
```

If using an Apache Isis [SimpleApp archetype](#), then the POM is already correctly configured.

3.3. Application Menu Layout

The actions of domain services are made available as an application menu bar. By default each domain service corresponds to a single menu on this menu bar, with its actions as the drop-down menu items. This is rarely exactly what is required, however. The [@MemberOrder](#) and [@DomainServiceLayout](#) annotations can be used to rearrange the placement of menu items.

The screenshots below are taken from [Estatio](#), an open source estate management application built using Apache Isis.

3.3.1. @DomainServiceLayout

Menus for domain services can be placed either on a primary, secondary or tertiary menu bar.

Within a single top-level menu (eg "Fixed Assets") there can be actions from multiple services. The Wicket viewer automatically adds a divider between each:

In the example above the top-level menu combines the actions from the **Properties**, **Units** and **FixedAssetRegistrations** services. The **Properties** service is annotated:

```
@DomainServiceLayout(
    named="Fixed Assets",
    menuBar = DomainServiceLayout.MenuBar.PRIMARY,
    menuOrder = "10.1"
)
public class Properties ... { ... }
```

while the **Units** service is annotated:

```

@DomainServiceLayout(
    named="Fixed Assets",
    menuBar = DomainServiceLayout.MenuBar.PRIMARY,
    menuOrder = "10.2"
)
public class Units ... { ... }

```

and similarly `FixedAssetRegistrations` is annotated:

```

@DomainServiceLayout(
    named="Fixed Assets",
    menuBar = DomainServiceLayout.MenuBar.PRIMARY,
    menuOrder = "10.3"
)
public class FixedAssetRegistrations ... { ... }

```

Note that in all three cases the value of the `named` attribute and the `menuBar` attribute is the same: "Fixed Assets" and PRIMARY. This means that all will appear on a "Fixed Assets" menu in the primary menu bar.

Meanwhile the value of `menuOrder` attribute is significant for two reasons:

- for these three services on the same ("Fixed Assets") top-level menu, it determines the relative order of their sections (`Properties` first, then `Units`, then `FixedAssetRegistrations`)
- it determines the placement of the top-level menu itself ("Fixed Assets") with respect to other top-level menus on the menu bar.

To illustrate this latter point, the next top-level menu on the menu bar, "Parties", is placed after "Fixed Assets" because the `menuOrder` of the first of its domain services, namely the `Parties` service, is higher than that for "Fixed Assets":

```

@DomainServiceLayout(
    named="Parties",
    menuBar = DomainServiceLayout.MenuBar.PRIMARY,
    menuOrder = "20.1"
)
public class Parties ... { ... }

```

Note that only the `menuOrder` of the *first* domain service is significant in placing the menus along the menu bar; thereafter the purpose of the `menuOrder` is to order the menu services sections on the menu itself.

3.3.2. Ordering menu actions

For a given service, the actions within a section on a menu is determined by the `@MemberOrder` annotation. Thus, for the `Units` domain service, its actions are annotated:

```

public class Units extends EstatioDomainService<Unit> {

    @MemberOrder(sequence = "1")
    public Unit newUnit( ... ) { ... }

    @MemberOrder(sequence = "2")
    public List<Unit> findUnits( ... ) { ... }

    @ActionLayout( prototype = true )
    @MemberOrder(sequence = "99")
    public List<Unit> allUnits() { ... }

    ...
}

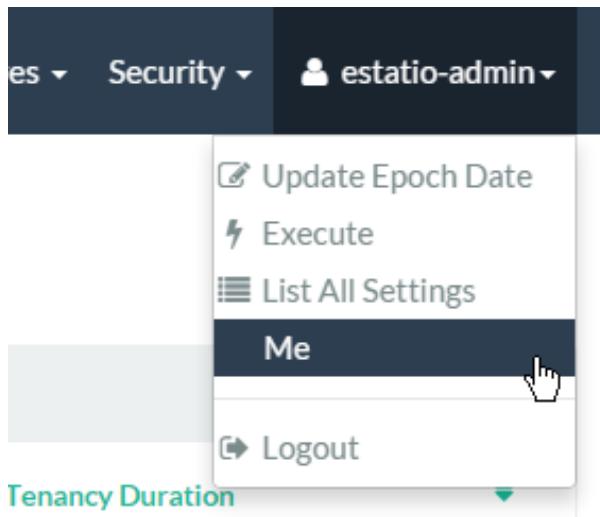

```

Note that the last is also a prototype action (meaning it is only displayed in SERVER_PROTOTYPE (=Wicket Development) mode). In the UI it is rendered in italics.

(It is possible to override this place of a given action by specifying `@MemberOrder(name="...")` where the name is that of a top-level menu. Prior to 1.8.0 this was the only way of doing things, as of 1.8.0 its use is not recommended).

3.3.3. Tertiary menubar

The tertiary menu bar consists of a single unnamed menu, rendered underneath the user's login, top right. This is intended primarily for actions pertaining to the user themselves, eg their account, profile or settings:

Domain services' actions can be associated with the tertiary menu using the same `@DomainServiceLayout` annotation. For example, the `updateEpochDate(...)` and `listAllSettings(...)` actions come from the following service:

```

@DomainServiceLayout(
    menuBar = DomainServiceLayout.MenuBar.TERTIARY,
    menuOrder = "10.1"
)
public class EstatioAdministrationService ... {

    @MemberOrder(sequence = "1")
    public void updateEpochDate( ... ) { ... }

    @MemberOrder(sequence = "2")
    public List<ApplicationSetting> listAllSettings() { ... }

    ...
}

```

Because the number of items on the tertiary menu is expected to be small and most will pertain to the current user, the viewer does *not* place dividers between actions from different services on the tertiary menu.

3.3.4. Isis Add-on modules

Some of the (non-ASF) [Isis Addons](#) modules also provide services whose actions appear in top-level menus.

The [security](#)'s module places its domain service menus in three top-level menus:

- its [ApplicationUsers](#), [ApplicationRoles](#), [ApplicationPermission](#), [ApplicationFeatureViewModels](#) and [ApplicationTenancies](#) domain services are all grouped together in a single "Security" top-level menu, on the SECONDARY menu bar
- its [SecurityModuleAppFixturesService](#) domain service, which allows the security modules' fixture scripts to be run, is placed on a "Prototyping" top-level menu, also on the SECONDARY menu bar
- its [MeService](#) domain service, which provides the [me\(\)](#) action, is placed on the TERTIARY menu bar.

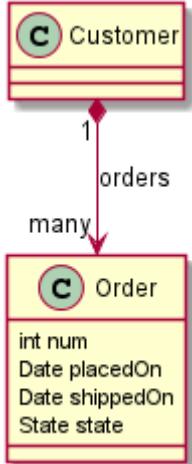

Meanwhile the [devutils](#) module places its actions - to download layouts and so forth - on a "Prototyping" top-level menu, on the SECONDARY menu bar.

Currently there is no facility to alter the placement of these services. However, their UI can be suppressed using security or using a [vetoing subscriber](#).

3.4. Table Columns

The optional [TableColumnOrderService](#) SPI service can be used to reorder columns in a table, either for a parented collection (owned by parent domain object) or a standalone collection (returned from an action invocation).

For example, suppose there is a [Customer](#) and an [Order](#):

The order of these properties of `Order`, when rendered in the context of its owning `Customer`, can be controlled using this implementation of `TableColumnOrderService`:

```

@DomainService(
    nature = NatureOfService.DOMAIN,
    menuOrder = "100"                                ①
)
public class TableColumnOrderServiceForCustomerOrders
    implements TableColumnOrderService {
    public List<String> orderParented(
        final Object parent,
        final String collectionId,
        final Class<?> collectionType,
        final List<String> propertyIds) {
        return parent instanceof Customer && "orders".equals(collectionId)
            ? Arrays.asList("num", "placedOn", "state", "shippedOn")
            : null;
    }
    public List<String> orderStandalone(
        final Class<?> collectionType,
        final List<String> propertyIds) {
        return null;
    }
}
  
```

① specifies the order in which the `TableColumnOrderService` implementations are called.

Chapter 4. Configuration Properties

Wicket configuration properties alter the way in which Apache Isis' Wicket viewer renders domain objects. They are typically stored in [WEB-INF/viewer_wicket.properties](#).

To tell Apache Isis that the Wicket viewer is in use (and should therefore search for the `viewer_wicket.properties` file), add the following to [WEB-INF/web.xml](#):

```
<context-param>
    <param-name>isis.viewers</param-name>
    <param-value>wicket</param-value>
</context-param>
```

If you prefer you can place all configuration properties into [WEB-INF/isis.properties](#) (the configuration properties from all config files are merged together).

Table 2. Wicket Viewer Configuration Properties

Property	Value (default value)	Description
<code>isis.viewer.wicket.ajaxDebugMode</code>	<code>true, false</code> (<code>false</code>)	whether the Wicket debug mode should be enabled.
<code>isis.viewer.wicket.bookmarkedPages</code>	+ve int (<code>15</code>)	number of pages to bookmark
<code>isis.viewer.wicket.breadcrumbs.showChooser</code>	<code>true, false</code> (<code>true</code>)	Whether to show chooser for Breadcrumbs
<code>isis.viewer.wicket.datePattern</code>	date format (<code>dd-MM-yyyy</code>)	The SimpleDateFormat used to render dates. For the date picker (which uses moment.js library), this is converted dynamically into the corresponding moment.js format.
<code>isis.viewer.wicket.dateTimePattern</code>	date/time format (<code>dd-MM-yyyy HH:mm</code>)	The SimpleDateFormat used to render date/times. For the date picker (which uses moment.js library), this is converted dynamically into the corresponding moment.js format.
<code>isis.viewer.wicket.datePicker.maxDate</code>	ISO format date (<code>2100-01-01T00:00:00.000Z</code>)	Specifies a maximum date after which dates may not be specified. See datepicker reference docs for further details. The string must be in ISO date format (see here for further details).
<code>isis.viewer.wicket.datePicker.minDate</code>	ISO format date (<code>1900-01-01T00:00:00.000Z</code>)	Specifies a minimum date before which dates may not be specified. See datepicker reference docs for further details. The string must be in ISO date format (see here for further details).

Property	Value (default value)	Description
<code>isis.viewer.wicket.disableDependentChoiceAutoSelection</code>	<code>true, false (false)</code>	For dependent choices, whether to automatically select the first dependent (eg subcategory) when the parameter on which it depends (category) changes.
<code>isis.viewer.wicket.disableModalDialogs</code>	<code>true, false (false)</code>	No longer supported.
<code>isis.viewer.wicket.liveReloadUrl</code>	URL	Specifies the URL if live reload is set up, eg: http://localhost:35729/livereload.js?snipver=1
<code>isis.viewer.wicket.maxTitleLengthInParentedTables</code>	+ve integer (12)	See discussion below .
<code>isis.viewer.wicket.maxTitleLengthInStandaloneTables</code>	+ve integer, (12)	See discussion below .
<code>isis.viewer.wicket.maxTitleLengthInTables</code>	+ve integer, (12)	See discussion below .
<code>isis.viewer.wicket.preventDoubleClickForFormSubmit</code>	<code>true, false (true)</code>	Whether to disable a form submit button after it has been clicked, to prevent users causing an error if they do a double click.
<code>isis.viewer.wicket.preventDoubleClickForNoArgAction</code>	<code>true, false (true)</code>	Whether to disable a no-arg action button after it has been clicked, to prevent users causing an error if they do a double click.
<code>isis.viewer.wicket.promptStyle</code>	<code>dialog, inline (inline)</code>	(1.15.0-SNAPSHOT) whether the prompt for editing a domain object property or invoking an action (associated with a property) is shown inline within the property's form, or instead shown in a modal dialog box. Can be overridden on a property-by-property basis using <code>@Property#promptStyle()</code> or <code>@Action#promptStyle()</code> .
<code>isis.viewer.wicket.redirectEvenIfSameObject</code>	<code>true, false (false)</code>	(1.15.0-SNAPSHOT) By default, an action invocation that returns the same object will result in the page being updated. The same is true for property edits. If this setting is enabled, then the viewer will always render to a new page. [NOTE] === Note that default behaviour is new in 1.15.0-SNAPSHOT, and provides a better UI. Setting this option retains the behaviour of the viewer pre-1.15.0. ===
<code>isis.viewer.wicket.regularCase</code>	<code>true, false (false)</code>	Ignored for 1.8.0+; in earlier versions forced regular case rather than title case in the UI

Property	Value (default value)	Description
<code>isis.viewer.wicket.replaceDisabledTagWithReadOnlyTag</code>	<code>true, false (true)</code>	Whether to replace 'disabled' tag with 'readonly' (for w3 spec-compliant browsers such as for Firefox and Chrome 54+) which prevent copy from 'disabled' fields.
<code>isis.viewer.wicket.rememberMe.cookieKey</code>	ascii chars (<code>isisWicketRememberMe</code>)	Cookie key holding the (encrypted) 'rememberMe' user/password. There is generally no need to change this. Valid values as per this StackOverflow answer .
<code>isis.viewer.wicket.rememberMe.encryptionKey</code>	any string (in prod, a random UUID each time)	Encryption key is used to encrypt the rememberMe user/password. Apache Isis leverages Apache Wicket's rememberMe support which holds remembered user/passwords in an encrypted cookie. If a hard-coded and publicly known value were to be used (as was the case prior to 1.13.0), then it would be possible for rememberMe user/password to be intercepted and decrypted, possibly compromising access. This configuration property therefore allows a private key to be specified, baked into the application. If no value is set then, in production, a random UUID will be used as the encryption key. The net effect of this fallback behaviour is that 'rememberMe' will work, but only until the webapp is restarted (after which the end-user will have to log in again). In prototype mode, though, a fixed key will still be used; this saves the developer having to login each time.
<code>isis.viewer.wicket.rememberMe.suppress</code>	<code>true, false (false)</code>	Whether to suppress "remember me" checkbox on the login page.
<code>isis.viewer.wicket.stripWicketTags</code>	<code>true, false (true)</code>	Whether to force Wicket tags to be stripped in prototype/development mode. See discussion below .
<code>isis.viewer.wicket.suppressPasswordReset</code>	<code>true, false (false)</code>	If user registration is enabled, whether to suppress the "password reset" link on the login page. See discussion below .
<code>isis.viewer.wicket.suppressRememberMe</code>	<code>true, false (false)</code>	(Deprecated in 1.13.0 , replaced by <code>rememberMe.suppress</code>). Whether to suppress "remember me" checkbox on the login page.
<code>isis.viewer.wicket.suppressSignUp</code>	<code>true, false (false)</code>	If user registration is enabled, whether to suppress the "sign up" link on the login page. See discussion below .

Property	Value (default value)	Description
<code>isis.viewer.wicket.timestampPattern</code>	date/time format (<code>yyyy-MM-dd HH:mm:ss.SSS</code>)	The <code>SimpleDateFormat</code> used to render timestamps.
<code>isis.viewer.wicket.themes.enabled</code>	comma separated list of bootswatch themes. Only applies if <code>themes.showChooser==true</code> . See discussion below .
<code>isis.viewer.wicket.themes.showChooser</code>	<code>true, false</code> (<code>false</code>)	Whether to show chooser for Bootstrap themes. See discussion below
<code>isis.viewer.wicket.useIndicatorForFormSubmit</code>	<code>true, false</code> (<code>true</code>)	Whether to show an indicator for a form submit button that it has been clicked.
<code>isis.viewer.wicket.useIndicatorForNoArgAction</code>	<code>true, false</code> (<code>true</code>)	Whether to show an indicator for a no-arg action button that it has been clicked.
<code>isis.viewer.wicket.wicketSourcePlugin</code>	<code>true, false</code> (<code>false</code>)	Whether the WicketSource plugin should be enabled; by default it is not enabled. Prior to 1.12.0 this was enabled by default for prototyping (not production). However it can significantly slow down rendering, hence the introduction of this configuration setting.

4.1. Abbreviating/suppressing titles in tables

Objects whose title is overly long can be cumbersome in titles. The Wicket viewer has a mechanism to automatically shorten the titles of objects specified using `@Title`. As an alternative/in addition, the viewer can also be configured to simply truncate titles longer than a certain length.

The properties themselves are:

```
isis.viewer.wicket.maxTitleLengthInStandaloneTables=20
isis.viewer.wicket.maxTitleLengthInParentedTables=8
```

If you wish to use the same value in both cases, you can also specify just:

```
isis.viewer.wicket.maxTitleLengthInTables=15
```

This is used as a fallback if the more specific properties are not provided.

If no properties are provided, then the Wicket viewer defaults to abbreviating titles to a length of [12](#).

4.2. Suppressing 'remember me'

The 'remember me' checkbox on the login page can be suppressed, if required, by setting a configuration flag.

4.2.1. Screenshots

With 'remember me' not suppressed (the default):

Security Module Example App

Login

Username

Password

Remember me

Sign in Reset

[Forgot your password?](#)

[Don't have an account? Sign up now.](#)

and with the checkbox suppressed:

Security Module Example App

Login

Username

Password

[Sign in](#) [Reset](#)

[Forgot your password?](#)

[Don't have an account? Sign up now.](#)

4.2.2. Configuration

To suppress the 'remember me' checkbox, add the following configuration flag:

```
isis.viewer.wicket.rememberMe.suppress=true
```

4.3. Suppressing 'sign up'

If user registration has been configured, then the Wicket viewer allows the user to sign-up a new account and to reset their password from the login page.

The 'sign up' link can be suppressed, if required, by setting a configuration flag.

4.3.1. Screenshots

With 'sign up' not suppressed (the default):

Security Module Example App

Login

Username

Password

Remember me

[Sign in](#) [Reset](#)

[Forgot your password?](#)

[Don't have an account? Sign up now.](#)

and with the link suppressed:

Security Module Example App

Login

Username

Password

Remember me

[Sign in](#) [Reset](#)

[Forgot your password?](#)

4.3.2. Configuration

To suppress the 'sign up' link, add the following configuration flag:

```
isis.viewer.wicket.suppressSignUp=true
```

4.3.3. See also

The [password reset link](#) can be suppressed in a similar manner.

4.4. Suppressing 'password reset'

If user registration has been configured, then the Wicket viewer allows the user to sign-up a new account and to reset their password from the login page.

The 'password reset' link can be suppressed, if required, by setting a configuration flag.

4.4.1. Screenshots

With 'password reset' not suppressed (the default):

Security Module Example App

Login

Username

Password

Remember me

[Forgot your password?](#)

[Don't have an account? Sign up now.](#)

and with the link suppressed:

Security Module Example App

Login

Username

Password

Remember me

Sign in Reset

Don't have an account? [Sign up now.](#)

4.4.2. Configuration

To suppress the 'password reset' link, add the following configuration flag:

```
isis.viewer.wicket.suppressPasswordReset=true
```

Typically this should be added to the `viewer_wicket.properties` file (in `WEB-INF`), though you can add to `isis.properties` if you wish.

4.4.3. See also

The [sign up link](#) can be suppressed in a similar manner.

4.5. Stripped Wicket tags

By default the Apache Isis Wicket viewer will always strip wicket tags. However, when running in prototype mode, this behaviour can be overridden using a configuration property:

```
isis.viewer.wicket.stripWicketTags=false
```

In 1.7.0 and earlier, the behaviour is different; the Apache Isis Wicket viewer will preserve wicket tags when running in Apache Isis' prototype/development mode, but will still strip wicket tags in Apache Isis' server/deployment mode.

We changed the behaviour in 1.8.0 because we found that Internet Explorer can be sensitive to the presence of Wicket tags.

4.6. Showing a theme chooser

The Wicket viewer uses [Bootstrap](#) styles and components (courtesy of the [Wicket Bootstrap](#) integration).

Unless a [default theme has been specified](#), the viewer uses the default bootstrap theme. However, the viewer can also be configured to allow the end-user to switch theme to another theme, in particular one of those provided by [bootswatch.com](#).

This is done using the following configuration property (in [WEB-INF/viewer_wicket.properties](#)):

```
isis.viewer.wicket.themes.showChooser=true
```

The screenshot shows a web browser window titled "Simple App". The address bar displays "localhost:8080/wicket/??". The page content is a simple informational page about the Simple App, mentioning it was generated using the SimpleApp archetype. On the right side, there is a vertical dropdown menu titled "bootstrap-theme" listing various Bootstrap themes: Amelia, Cerulean, Cosmo, Cyborg, Darkly, Flatly (which is highlighted), Journal, Lumen, Paper, Readable, Sandstone, Simplex, Slate, Spacelab, Superhero, United, and Yeti. At the bottom of the page, there is a footer with links to "Powered by: Apache Isis™", "About", and "Change theme ▾".

Figure 1. Example 1

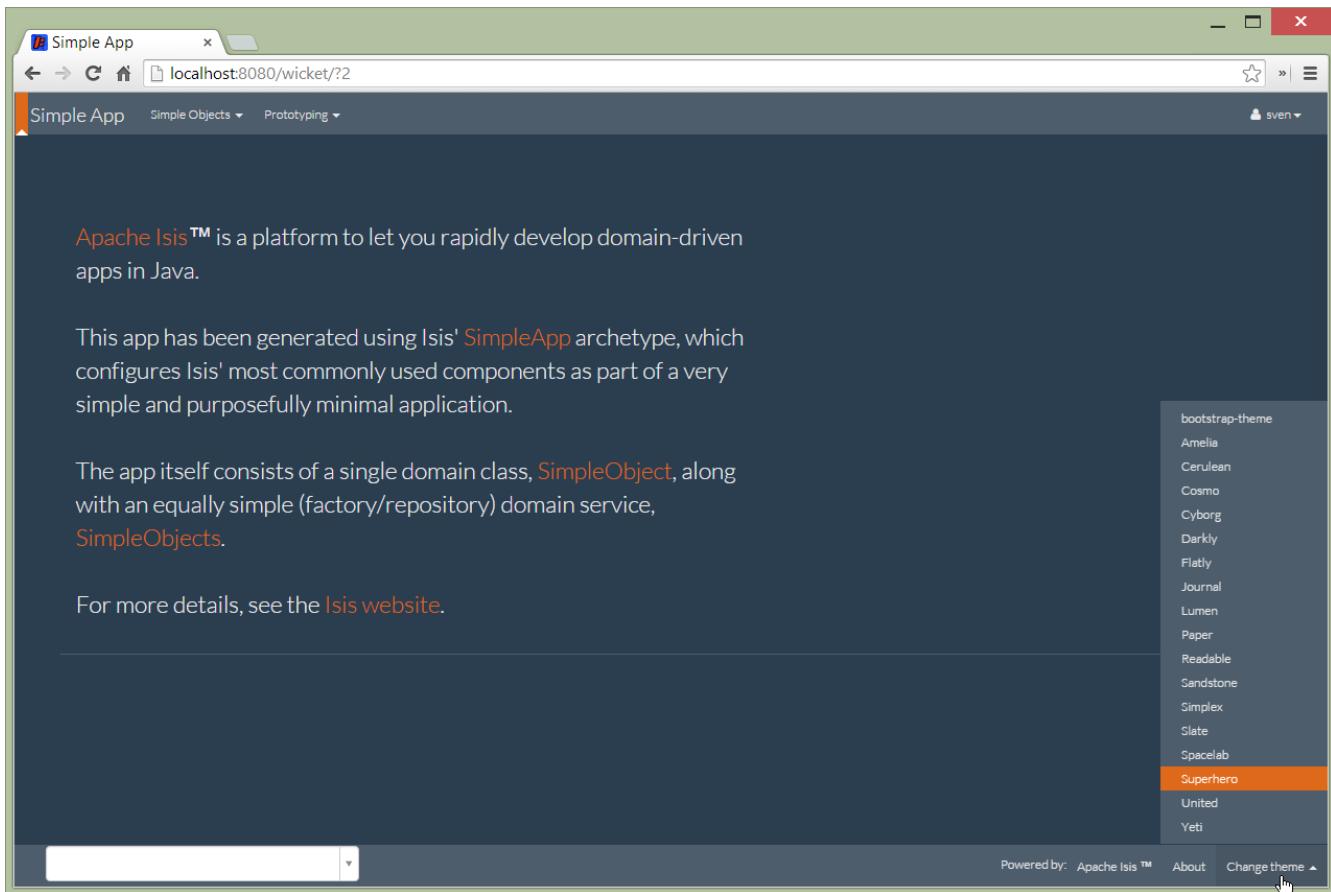

Figure 2. Example 2:

It is also possible to restrict the themes shown to some subset of those in bootswatch. This is done using a further property:

```
isis.viewer.wicket.themes.enabled=bootstrap-theme,Cosmo,Flatly,Darkly,Sandstone,United
```

where the value is the list of themes (from bootswatch.com) to be made available.

You can also develop and install a custom themes (eg to fit your company's look-n-feel/interface guidelines); see the [Extending](#) chapter for further details.

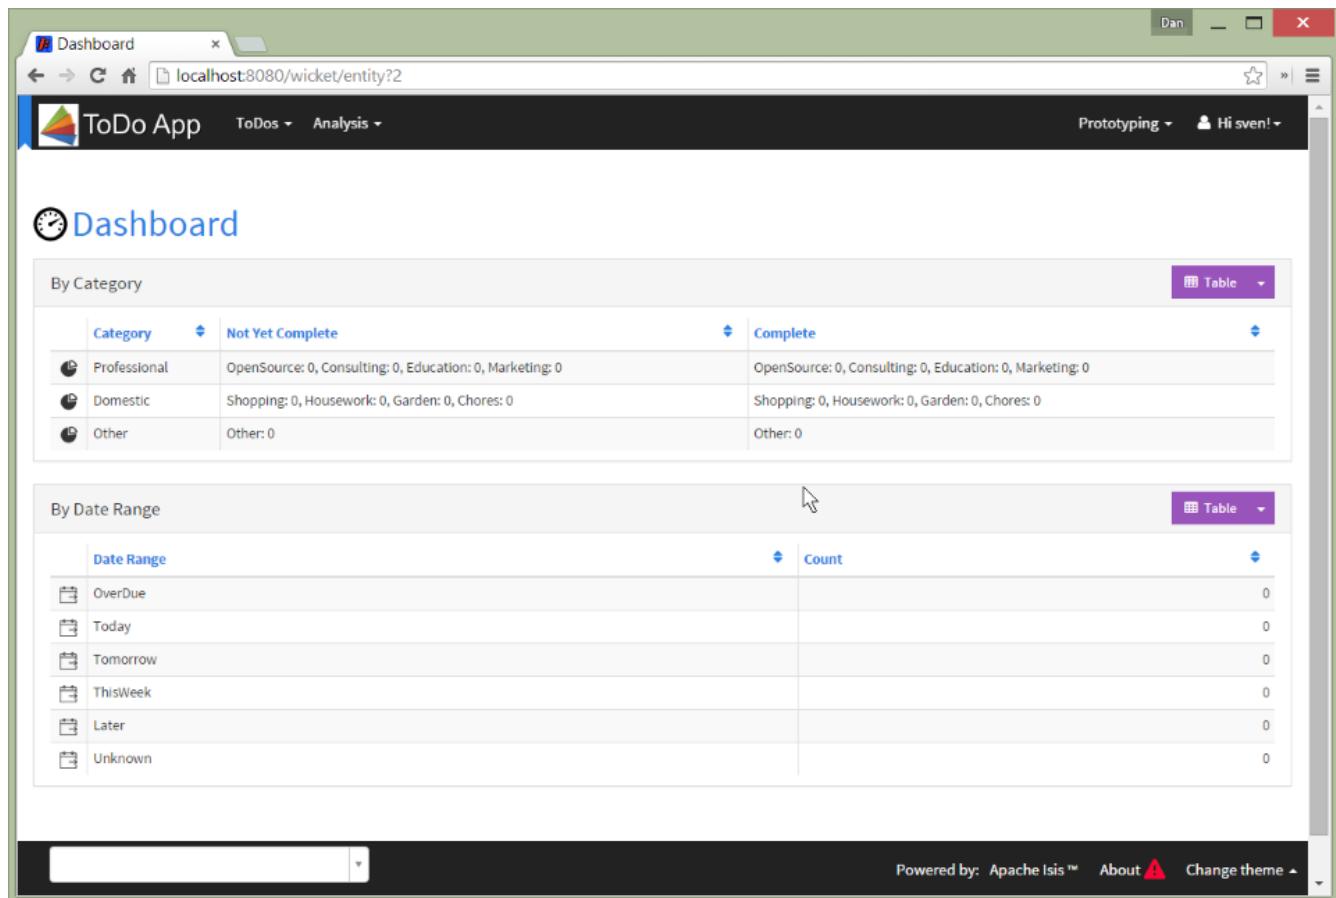

Chapter 5. Customisation

5.1. Brand logo

By default the Wicket viewer will display the application name top-left in the header menu. This can be changed to display a png logo instead.

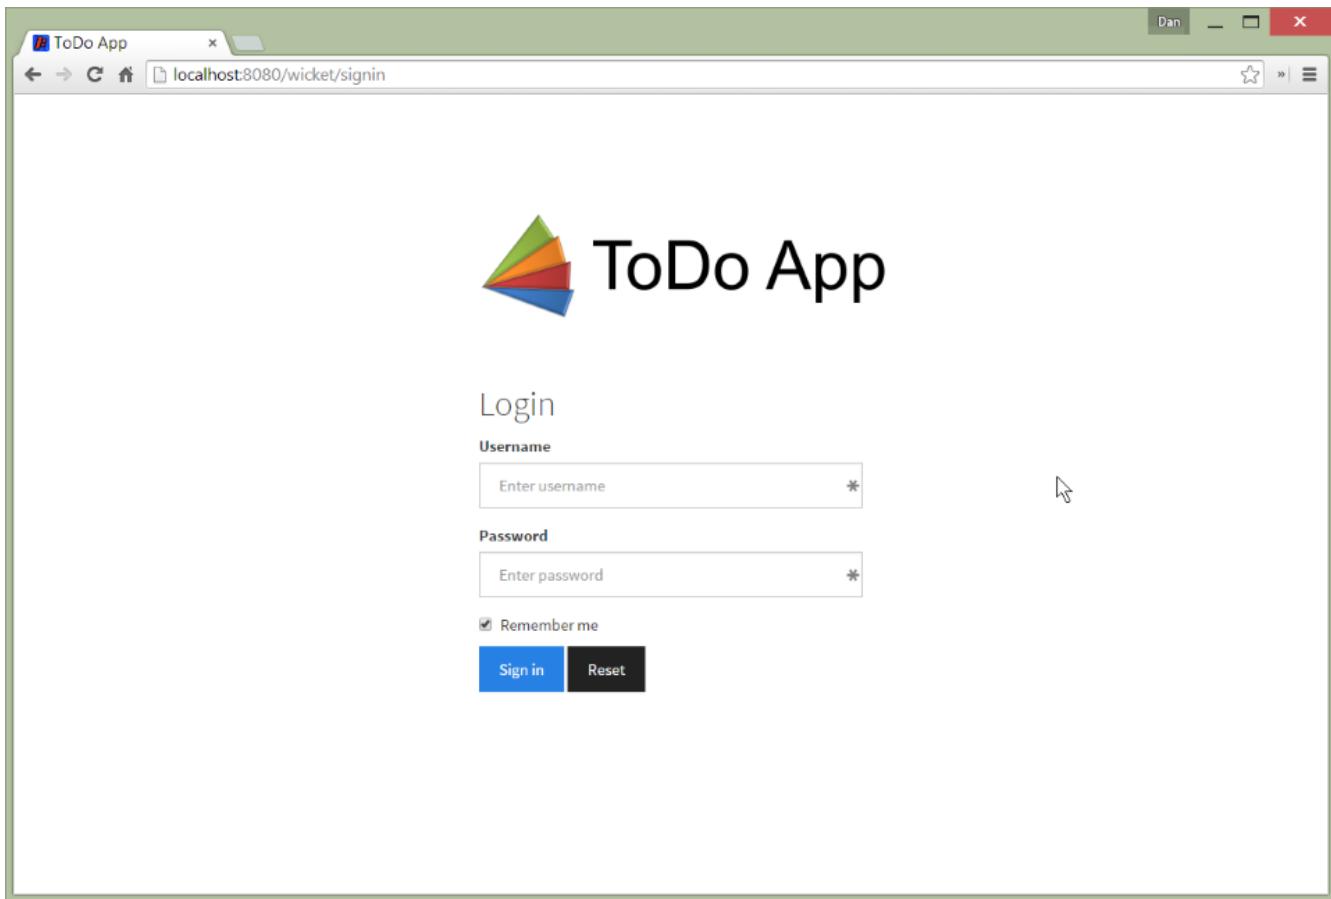

5.1.1. Screenshots

The screenshot below shows the Isis addons example [todoapp](#) (not ASF) with a 'brand logo' image in its header:

The screenshot displays a web browser window for the 'ToDo App' application. The title bar shows 'Dashboard' and the URL 'localhost:8080/wicket/entity?2'. The header includes a 'ToDo App' logo, navigation links for 'Todos' and 'Analysis', and a user profile 'Hi sven!'. Below the header, there are two main sections: 'By Category' and 'By Date Range', each presented as a table. The 'By Category' table has columns for 'Category' (Professional, Domestic, Other), 'Not Yet Complete' (OpenSource: 0, Consulting: 0, Education: 0, Marketing: 0), and 'Complete' (OpenSource: 0, Consulting: 0, Education: 0, Marketing: 0). The 'By Date Range' table has columns for 'Date Range' (OverDue, Today, Tomorrow, ThisWeek, Later, Unknown) and 'Count' (0, 0, 0, 0, 0, 0). At the bottom of the page, there is a footer bar with links for 'Powered by: Apache Isis™', 'About', and 'Change theme'.

A custom brand logo (typically larger) can also be specified for the signin page:

5.1.2. Configuration

In the application-specific subclass of `IsisWicketApplication`, bind:

- a string with name "brandLogoHeader" to the URL of a header image. A size of 160x40 works well.
- a string with name "brandLogoSignin" to the URL of a image for the sign-in page. A size of 400x100 works well.

For example:

```

@Override
protected Module newIsisWicketModule() {
    final Module isisDefaults = super.newIsisWicketModule();

    final Module overrides = new AbstractModule() {
        @Override
        protected void configure() {
            ...
            bind(String.class).annotatedWith(Names.named("brandLogoHeader"))
                .toInstance("/images/todoapp-logo-header.png");
            bind(String.class).annotatedWith(Names.named("brandLogoSignin"))
                .toInstance("/images/todoapp-logo-signin.png");
            ...
        }
    };
}

return Modules.override(isisDefaults).with(overrides);
}

```

If the logo is hosted locally, add to the relevant directory (eg `src/main/webapp/images`). It is also valid for the URL to be absolute.

You may also wish to tweak the `application.css`. For example, a logo with height 40px works well with the following:

```

.navbar-brand img {
    margin-top: -5px;
    margin-left: 5px;
}

```

5.2. Specifying a default theme

The Apache Isis Wicket viewer uses `Bootstrap` styles and components (courtesy of the [Wicket Bootstrap](#) integration).

Unless specified otherwise, the viewer uses the default bootstrap theme. However, this can be changed by overriding `init()` in the application's subclass of `IsisWicketApplication`. For example, to set the `bootswatch.com flatly` theme as the default, use:

```

@Override
protected void init() {
    super.init();
    IBootstrapSettings settings = Bootstrap.getSettings();
    settings.setThemeProvider(new BootswatchThemeProvider(BootswatchTheme.Flatly));
}

```

If you have developed a custom Bootstrap theme (as described [here](#)) then this can also be specified using the [Wicket Bootstrap API](#).

5.3. Welcome page

It's possible to customize the application name, welcome message and about message can also be customized. This is done by adjusting the Guice bindings (part of Apache Isis' bootstrapping) in your custom subclass of `IsisWicketApplication`:

```
public class MyAppApplication extends IsisWicketApplication {  
    @Override  
    protected Module newIsisWicketModule() {  
        final Module isisDefaults = super.newIsisWicketModule();  
        final Module myAppOverrides = new AbstractModule() {  
            @Override  
            protected void configure() {  
                ...  
                bind(String.class)  
                    .annotatedWith(Names.named("applicationName"))  
                    .toInstance("My Wonderful App");  
                bind(String.class)  
                    .annotatedWith(Names.named("welcomeMessage"))  
                    .toInstance(readLines("welcome.html"));           ①  
                bind(String.class)  
                    .annotatedWith(Names.named("aboutMessage"))  
                    .toInstance("My Wonderful App v1.0");  
                ...  
            }  
        };  
  
        return Modules.override(isisDefaults).with(myAppOverrides);  
    }  
}
```

① the `welcome.html` file is resolved relative to `src/main/webapp`.

5.4. About page

Isis' Wicket viewer has an About page that, by default, will provide a dump of the JARs that make up the webapp. This page will also show the manifest attributes of the WAR archive itself, if there are any. One of these attributes may also be used as the application version number.

5.4.1. Screenshot

Here's what the About page looks like with this configuration added:

QuickStart (20130311-1402)

JAR MANIFEST ATTRIBUTES

Web archive (war file)

```
Build-Time: 20130311-1402
Build-Java: 1.6.0_43
Build-OS: Windows 7

```

Note that this screenshot shows an earlier version of the [Wicket viewer](#) UI (specifically, pre 1.8.0).

Note that the **Build-Time** attribute has been used as the version number. The Wicket viewer is hard-coded to search for specific attributes and use as the application version. In order, it searches for:

- **Implementation-Version**
- **Build-Time**

If none of these are found, then no version is displayed.

5.4.2. Configuration

This configuration is included within the [SimpleApp archetype](#).

Adding attributes to the WAR's manifest

Add the following to the webapp's **pom.xml** (under `<build>/<plugins>`):

```

<plugin>
    <groupId>org.codehaus.mojo</groupId>
    <artifactId>build-helper-maven-plugin</artifactId>
    <version>1.5</version>
    <executions>
        <execution>
            <phase>validate</phase>
            <goals>
                <goal>maven-version</goal>
            </goals>
        </execution>
    </executions>
</plugin>

<plugin>
    <artifactId>maven-war-plugin</artifactId>
    <configuration>
        <archive>
            <manifest>
                <addDefaultImplementationEntries>
true</addDefaultImplementationEntries>
                </manifest>
                <manifestEntries>
                    <Build-Time>${maven.build.timestamp}</Build-Time>
                    <Build-Number>${buildNumber}</Build-Number>
                    <Build-Host>${agent.name}</Build-Host>
                    <Build-User>${user.name}</Build-User>
                    <Build-Maven>Maven ${maven.version}</Build-Maven>
                    <Build-Java>${java.version}</Build-Java>
                    <Build-OS>${os.name}</Build-OS>
                    <Build-Label>${project.version}</Build-Label>
                </manifestEntries>
            </archive>
        </configuration>
        <executions>
            <execution>
                <phase>package</phase>
                <goals>
                    <goal>war</goal>
                </goals>
                <configuration>
                    <classifier>${env}</classifier>
                </configuration>
            </execution>
        </executions>
    </plugin>

```

If you then build the webapp from the Maven command line (`mvn clean package`), then the WAR should contain a `META-INF/MANIFEST.MF` with those various attribute entries.

Exporting the attributes into the app

The manifest attributes are provided to the rest of the application by way of the Wicket viewer's integration with Google Guice.

In your subclass of `IsisWicketApplication`, there is a method `newIsisWicketModule()`. In this method you need to bind an `InputStream` that will read the manifest attributes. This is all boilerplate so you can just copy-n-paste:

```
@Override  
protected Module newIsisWicketModule() {  
    ...  
    final Module simpleappOverrides = new AbstractModule() {  
        @Override  
        protected void configure() {  
            ...  
            bind(InputStream.class)  
                .annotatedWith(Names.named("metaInfManifest"))  
                .toProvider(Providers.of(  
                    getServletContext().getResourceAsStream("/META-INF/MANIFEST.MF"))  
);  
        }  
    };  
    ...  
}
```

With that you should be good to go!

5.5. Tweaking CSS classes

The HTML generated by the Wicket viewer include plenty of CSS classes so that you can easily target the required elements as required. For example, you could use CSS to suppress the entity's icon alongside its title. This would be done using:

```
.entityIconAndTitlePanel a img {  
    display: none;  
}
```

These customizations should generally be added to `application.css`; this file is included by default in every webpage served up by the Wicket viewer.

5.5.1. Individual members

For example, the `ToDoItem` object of the Isis addons example `todoapp` (not ASF) has a `notes` property. The HTML for this will be something like:

```

<div>
  <div class="property ToDoItem-notes">
    <div class="multiLineStringPanel scalarNameAndValueComponentType">
      <label for="id83" title="">
        <span class="scalarName">Notes</span>
        <span class="scalarValue">
          <textarea
            name=
"middleColumn:memberGroup:1:properties:4:property:scalarIfRegular:scalarValue"
            disabled="disabled"
            id="id83" rows="5" maxlength="400" size="125"
            title="">
          </textarea>
          <span>
            </span>
          </label>
        </div>
      </div>
    </div>
  </div>

```

The `application.css` file is the place to add application-specific styles. By way of an example, if (for some reason) we wanted to completely hide the notes value, we could do so using:

```

div.ToDoItem-notes span.scalarValue {
  display: none;
}

```

You can use a similar approach for collections and actions.

5.5.2. Custom CSS styles

The above technique works well if you know the class member to target, but you might instead want to apply a custom style to a set of members. For this, you can use the `@CssClass`.

For example, in the `ToDoItem` class the following annotation (indicating that this is a key, important, property) :

```

@PropertyLayout(cssClass="x-myapp-highlight")
public LocalDate getDueBy() {
  return dueBy;
}

```

would generate the HTML:

```
<div>
  <div class="property ToDoItem-dueBy x-myapp-highlight">
    ...
  </div>
</div>
```

This can then be targeted, for example using:

```
div.x-myapp-highlight span.scalarName {
  color: red;
}
```

Note also that instead of using `@PropertyLayout(cssClass=…)` annotation, you can also specify the CSS style using a [layout file](#).

5.5.3. Table columns

Sometimes you may want to apply styling to specific columns of tables. For example, you might want to adjust width so that for certain properties have more (or less) room than they otherwise would; or you might want to hide the column completely. This also applies to the initial icon/title column.

There is also the issue of scoping:

- You may wish the style to apply globally: that is, dependent on the type of entity being rendered in the table, irrespective of the page on which it is shown.
- Alternatively, you may wish to target the CSS for a table as rendered either as a parented collection (owned by some other entity) or rendered as a standalone collection (the result of invoking an action).

In each of these cases the Wicket viewer adds CSS classes either to containing `divs` or to the `<th>` and `<td>` elements of the table itself so that it can custom styles can be appropriately targeted.

Applying styles globally

Every rendered collection containing a domain class will be wrapped in a `<div>` that lists that domain class (in CSS safe form). For example:

```
<div class="entityCollection com-mycompany-myapp-Customer">
...
<table>
  <tr>
    <th class="title-column">...</th>
    <th class="firstName">...</th>
    <th class="lastName">...</th>
    ...
  </tr>
  <tr>
    <td class="title-column">...</td>
    <td class="firstName">...</td>
    <td class="lastName">...</td>
    ...
  </tr>
  ...
</table>
...
</div>
```

Using this, the `lastName` property could be targeted using:

```
.com-mycompany-myapp-Customer th.lastName {
  width: 30%;
}
```

Parented collections

Parented collections will be wrapped in `<div>`s that identify both the entity type and also the collection Id. For example:

```

<div class="entityPage com-mycompany-myapp-Customer">          ①
  ...
    <div class="orders">
      <table>
        <tr>
          <th class="title-column">...</th>
          <th class="productRef">...</th>
          <th class="quantity">...</th>
        ...
        </tr>
        <tr>
          <td class="title-column">...</td>
          <td class="productRef">...</td>
          <td class="quantity">...</td>
        ...
        </tr>
      ...
    </table>
  ...
</div>
...

```

① the parent class identifier

② the collection identifier. This element's class also has the entity type within the collection (as discussed above).

Using this, the `productRef` property could be targeted using:

```
.com-mycompany-myapp-Customer orders td.productRef {
  font-style: italic;
}
```

Standalone collections

Standalone collections will be wrapped in a `<div>` that identifies the action invoked. For example:

```

<div class="standaloneCollectionPage">
    <div class="com-mycompany-myapp-Customer_mostRecentOrders ..." ①>
        ...
        <div class="orders">
            <table>
                <tr>
                    <th class="title-column">...</th>
                    <th class="productRef">...</th>
                    <th class="quantity">...</th>
                ...
                </tr>
                <tr>
                    <td class="title-column">...</td>
                    <td class="productRef">...</td>
                    <td class="quantity">...</td>
                ...
                </tr>
                ...
            </table>
        ...
    </div>
    ...
</div>

```

- ① action identifier. This element's class also identifies the entity type within the collection (as discussed above).

Using this, the `quantity` property could be targeted using:

```
.com-mycompany-myapp-Customer_mostRecentOrders td.quantity {
    font-weight: bold;
}
```

5.6. Cheap-n-cheerful theme

The application name (as defined in the `IsisWicketApplication` subclass) is also used (in sanitized form) as the CSS class in a `<div>` that wraps all the rendered content of every page.

For example, if the application name is "ToDo App", then the `<div>` generated is:

```

<div class="todo-app">
    ...
</div>

```

You can therefore use this CSS class as a way of building your own "theme" for the various elements of the wicket viewer pages.

Alternatively you could "do it properly" and create your [own Bootstrap theme](#), as described in the [Extending](#) chapter.

5.7. Using a different CSS file

If for some reason you wanted to name the CSS file differently (eg `stylesheets/myapp.css`), then adjust the Guice bindings (part of Apache Isis' bootstrapping) in your custom subclass of [IsisWicketApplication](#):

```
public class MyAppApplication extends IsisWicketApplication {  
    @Override  
    protected Module newIsisWicketModule() {  
        final Module isisDefaults = super.newIsisWicketModule();  
        final Module myAppOverrides = new AbstractModule() {  
            @Override  
            protected void configure() {  
                ...  
                bind(String.class)  
                    .annotatedWith(Names.named("applicationCss"))  
                    .toInstance("stylesheets/myapp.css");  
                ...  
            }  
        };  
  
        return Modules.override(isisDefaults).with(myAppOverrides);  
    }  
}
```

As indicated above, this file is resolved relative to `src/main/webapp`.

5.8. Custom Javascript

The Wicket viewer ships with embedded JQuery, so this can be leveraged to perform arbitrary transformations of the rendered page (eg to run some arbitrary JQuery on page load).

Just because something is possible, it doesn't necessarily mean we encourage it. Please be aware that there is no formal API for any custom javascript that you might implement to target; future versions of Apache Isis might break your code.

If possible, consider using the [ComponentFactory](#) API described in the [Extending](#) chapter.

To register your Javascript code, adjusting the Guice bindings (part of Apache Isis' bootstrapping) in your custom subclass of [IsisWicketApplication](#):

```

public class MyAppApplication extends IsisWicketApplication {
    @Override
    protected Module newIsisWicketModule() {
        final Module isisDefaults = super.newIsisWicketModule();
        final Module myAppOverrides = new AbstractModule() {
            @Override
            protected void configure() {
                ...
                bind(String.class)
                    .annotatedWith(Names.named("applicationJs"))
                    .toInstance("scripts/application.js");
                ...
            }
        };
        return Modules.override(isisDefaults).with(myAppOverrides);
    }
}

```

Currently only one such `.js` file can be registered.

5.9. Auto-refresh page

This requirement from the users mailing list:

<div class="extended-quote-first"><p>Suppose you want to build a monitoring application, eg for an electricity grid. Data is updated in the background (eg via the Restful Objects REST API). What is needed is the ability to show an entity that includes a map, and have it auto-refresh every 5 seconds or so. </p></div>

Here's one (somewhat crude, but workable) way to accomplish this.

- First, update the domain object to return custom CSS:

```

public class MyDomainObject {
    ...
    public String cssClass() {return "my-special-auto-updating-entity"; }
    ...
}

```

- Then, use javascript in `webapp/src/main/webapp/scripts/application.js` to reload:

```

$(function() {
    if ($("#.my-special-auto-updating-entity").length) {
        setTimeout(function() {document.location.reload();}, 5000); // 1000 is 5
        sec
    }
});

```

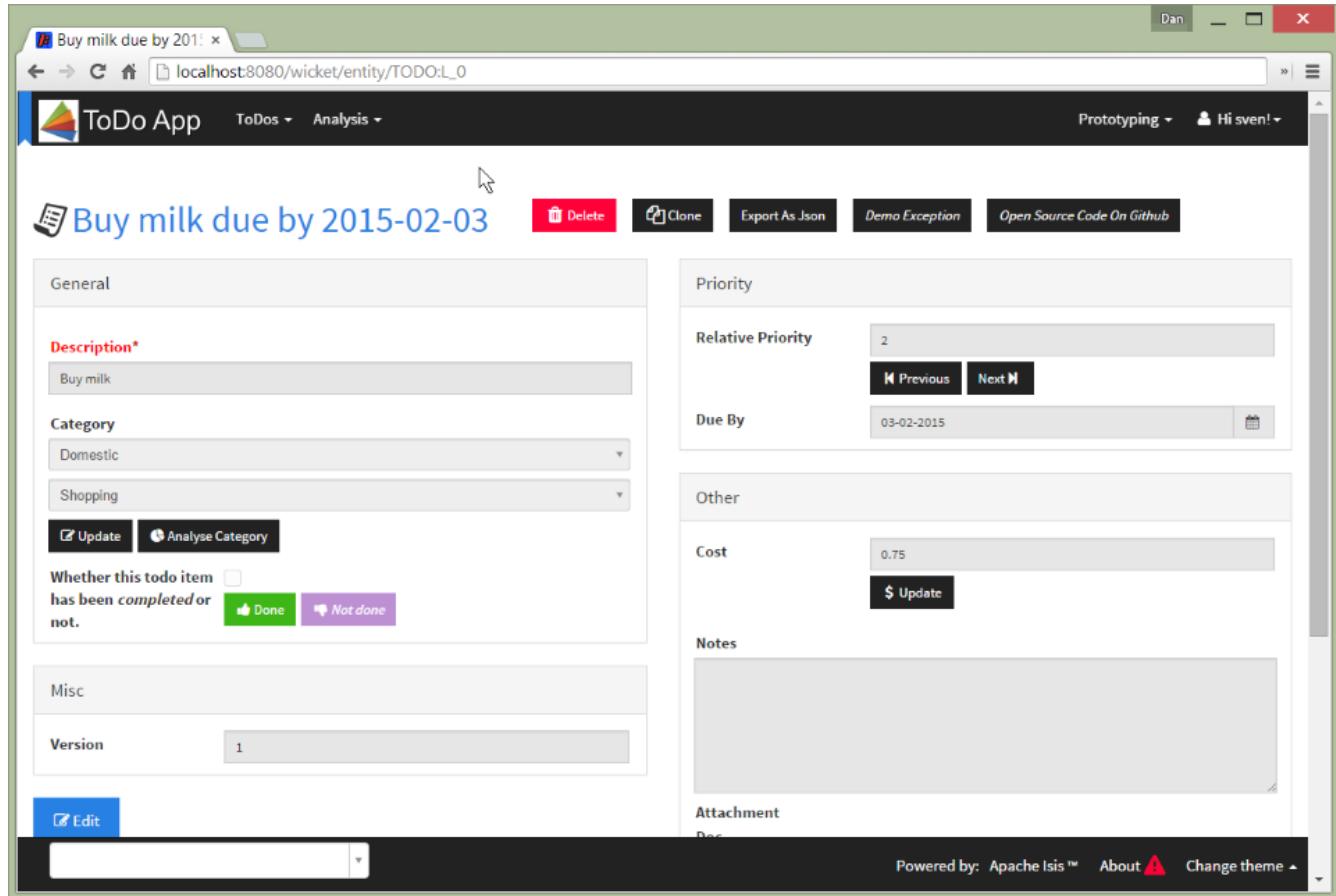

5.10. Embedded View

The Wicket viewer provides some support such that an Isis application can be embedded within a host webapp, for example within an iframe.

Currently this support consists simply of being able to suppress the header and/or footer.

5.10.1. Screenshots

For example, the regular view is:

With the header and footer both suppressed only the main content is shown:

The screenshot shows a Wicket application interface for managing a todo item. The main title is "Buy milk due by 2015-02-03". The interface is divided into several sections:

- General:** Description is "Buy milk". Category is set to "Domestic".
- Priority:** Relative Priority is 2. Due By is set to 03-02-2015.
- Other:** Cost is 0.75.
- Notes:** An empty text area for notes.

Action buttons include Delete, Clone, Export As Json, Demo Exception, Open Source Code On Github, Update, Analyse Category, Done, and Not done.

It is also possible to suppress just the header, or just the footer.

5.10.2. Request parameters

To suppress the header, add the following as a request parameter:

```
isis.no.header
```

and to suppress the footer, add the following as a request parameter:

```
isis.no.footer
```

For example,

```
http://localhost:8080/wicket/entity/TODO:0?isis.no.header&isis.no.footer
```

Chapter 6. Extending the Viewer

The Wicket viewer allows you to customize the GUI in several (progressively more sophisticated) ways:

- by [tweaking the UI using CSS](#)
- by [tweaking the UI using Javascript](#)
- by writing a [custom bootstrap theme](#)
- by [replacing elements of the page](#) using the [ComponentFactory](#) interface
- by implementing [replacement page implementations](#) for the standard page types

The first two of these options are discussed in the [Wicket viewer](#) chapter. This chapter describes the remaining "heavier-weight/more powerful" options.

The chapter wraps up with a technique for prototyping, allowing user/passwords to be specified as query arguments.

6.1. Custom Bootstrap theme

The Apache Isis Wicket viewer uses [Bootstrap](#) styles and components (courtesy of the [Wicket Bootstrap](#) integration).

By default the viewer uses the default bootstrap theme. It is possible to configure the Wicket viewer to allow the user to [select other themes](#) provided by [bootswatch.com](#), and if required one of these can be [set as the default](#).

However, you may instead want to write your own custom theme, for example to fit your company's look-n-feel/interface guidelines. This is done by implementing [Wicket Bootstrap](#)'s `de.agilecoders.wicket.core.settings.ITheme` class. This defines:

- the name of the theme
- the resources it needs (the CSS and optional JS and/or fonts), and
- optional urls to load them from a Content Delivery Network (CDN).

To make use of the custom `ITheme` the application should register it by adding the following snippet in (your application's subclass of) `IsisWicketApplication`:

```
public void init() {  
    ...  
    IBootstrapSettings settings = new BootstrapSettings();  
    ThemeProvider themeProvider = new SingleThemeProvider(new MyTheme());  
    settings.setThemeProvider(themeProvider);  
    Bootstrap.install(getClass(), settings);  
}
```

6.2. Replacing page elements

Replacing elements of the page is the most powerful general-purpose way to customize the look-and-feel of the viewer. Examples at the (non-ASF) [Isis Add-ons](#) include the [gmap3](#) extension, the [calendar](#) extension, the [excel download](#) and the [wickedcharts](#) charting integration.

The pages generated by Apache Isis' Wicket viewer are built up of numerous elements, from fine-grained widgets for property/parameter fields, to much larger components that take responsibility for rendering an entire entity entity, or a collection of entities. Under the covers these are all implementations of the the Apache Wicket [Component](#) API. The larger components delegate to the smaller, of course.

6.2.1. How the viewer selects components

Components are created using Apache Isis' [ComponentFactory](#) interface, which are registered in turn through the [ComponentFactoryRegistrar](#) interface. Every component is categorized by type (the [ComponentType](#) enum), and Apache Isis uses this to determine which [ComponentFactory](#) to use. For example, the [ComponentType.BOOKMARKED_PAGES](#) is used to locate the [ComponentFactory](#) that will build the bookmarked pages panel.

Each factory is also handed a model (an implementation of [org.apache.wicket.IModel](#)) appropriate to its [ComponentType](#); this holds the data to be rendered. For example, [ComponentType.BOOKMARKED_PAGES](#) is given a [BookmarkedPagesModel](#), while [ComponentType.SCALAR_NAME_AND_VALUE](#) factories are provided a model of type of type [ScalarModel](#).

In some cases there are several factories for a given [ComponentType](#); this is most notably the case for [ComponentType.SCALAR_NAME_AND_VALUE](#). After doing a first pass selection of candidate factories by [ComponentType](#), each factory is then asked if it [appliesTo\(Model\)](#). This is an opportunity for the factory to check the model itself to see if the data within it is of the appropriate type.

Thus, the [BooleanPanelFactory](#) checks that the [ScalarModel](#) holds a boolean, while the [JodaLocalDatePanelFactory](#) checks to see if it holds [org.joda.time.LocalDate](#).

There will typically be only one [ComponentFactory](#) capable of rendering a particular [ComponentType](#)/[ScalarModel](#) combination; at any rate, the framework stops as soon as one is found.

There is one refinement to the above algorithm where multiple component factories might be used to render an object; this is discussed in [Additional Views of Collections](#), below.

6.2.2. How to replace a component

This design (the [chain of responsibility](#) design pattern) makes it quite straightforward to change the rendering of any element of the page. For example, you might switch out Apache Isis' sliding bookmark panel and replace it with one that presents the bookmarks in some different fashion.

First, you need to write a [ComponentFactory](#) and corresponding [Component](#). The recommended approach is to start with the source of the [Component](#) you want to switch out. For example:

```

public class MyBookmarkedPagesPanelFactory extends ComponentFactoryAbstract {
    public MyBookmarkedPagesPanelFactory() {
        super(ComponentType.BOOKMARKED_PAGES);
    }
    @Override
    public ApplicationAdvice appliesTo(final IModel<?> model) {
        return appliesIf(model instanceof BookmarkedPagesModel);
    }
    @Override
    public Component createComponent(final String id, final IModel<?> model) {
        final BookmarkedPagesModel bookmarkedPagesModel = (BookmarkedPagesModel)
model;
        return new MyBookmarkedPagesPanel(id, bookmarkedPagesModel);
    }
}

```

and

```

public class MyBookmarkedPagesPanel
    extends PanelAbstract<BookmarkedPagesModel> {
    ...
}

```

Here `PanelAbstract` ultimately inherits from `org.apache.wicket.Component`. Your new `Component` uses the information in the provided model (eg `BookmarkedPagesModel`) to know what to render.

Next, you will require a custom implementation of the `ComponentFactoryRegistrar` that registers your custom `ComponentFactory` as a replacement:

```

@Singleton
public class MyComponentFactoryRegistrar extends ComponentFactoryRegistrarDefault {
    @Override
    public void addComponentFactories(ComponentFactoryList componentFactories) {
        super.addComponentFactories(componentFactories);
        componentFactories.add(new MyBookmarkedPagesPanelFactory());
    }
}

```

This will result in the new component being used instead of (that is, discovered prior to) Isis' default implementation.

Previously we suggested using "replace" rather than "add"; however this has unclear semantics for some component types; see [ISIS-996](#).

Finally (as for other customizations), you need to adjust the Guice bindings in your custom subclass of `IsisWicketApplication`:

```

public class MyAppApplication extends IsisWicketApplication {
    @Override
    protected Module newIsisWicketModule() {
        final Module isisDefaults = super.newIsisWicketModule();
        final Module myAppOverrides = new AbstractModule() {
            @Override
            protected void configure() {
                ...
                bind(ComponentFactoryRegistrar.class)
                    .to(MyComponentFactoryRegistrar.class);
                ...
            }
        };
        return Modules.override(isisDefaults).with(myAppOverrides);
    }
}

```

6.2.3. Additional Views of Collections

As explained above, in most cases Apache Isis' Wicket viewer will search for the first `ComponentFactory` that can render an element, and use it. In the case of (either standalone or parented) collections, though, Apache Isis will show all available views.

For example, out-of-the-box Apache Isis provides a table view, a summary view (totals/sums/averages of any data), and a collapsed view (for `@Render(LAZILY)` collections). These are selected by clicking on the toolbar by each collection.

Additional views though could render the objects in the collection as a variety of ways. Indeed, some third-party implementations already exist:

- [excel integration](#) (collection as a downloadable excel spreadsheet)
- [google maps v3 integration](#) (render any objects with a location on a map)
- [wicked charts integration](#) (barchart of any data)
- [full calendar integration](#) (render any objects with date properties on a calendar)

Registering these custom views is just a matter of adding the appropriate Maven module to the classpath. Apache Isis uses the JDK `ServiceLoader` API to automatically discover and register the `ComponentFactory` of each such component.

If you want to write your own alternative component and auto-register, then include a file `META-INF/services/org.apache.isis.viewer.wicket.ui.ComponentFactory` whose contents is the fully-qualified class name of the custom `ComponentFactory` that you have written.

Wicket itself has lots of components available at its [wicketstuff.org](#) companion website; you might find some of these useful for your own customizations.

6.2.4. Custom object view (eg dashboard)

One further use case in particular is worth highlighting; the rendering of an entire entity. Normally entities this is done using `EntityCombinedPanelFactory`, this being the first `ComponentFactory` for the `ComponentType.ENTITY` that is registered in Apache Isis default `ComponentFactoryRegistrarDefault`.

You could, though, register your own `ComponentFactory` for entities that is targeted at a particular class of entity - some sort of object representing a dashboard, for example. It can use the `EntityModel` provided to it to determine the class of the entity, checking if it is of the appropriate type. Your custom factory should also be registered before the `EntityCombinedPanelFactory` so that it is checked prior to the default `EntityCombinedPanelFactory`:

```
@Singleton
public class MyComponentFactoryRegistrar extends ComponentFactoryRegistrarDefault {
    @Override
    public void addComponentFactories(ComponentFactoryList componentFactories) {
        componentFactories.add(new DashboardEntityFactory());
        ...
        super.addComponentFactories(componentFactories);
        ...
    }
}
```

6.3. Custom pages

In the vast majority of cases customization should be sufficient by [replacing elements of a page](#). However, it is also possible to define an entirely new page for a given page type.

Isis defines eight page types (see the `org.apache.isis.viewer.wicket.model.models.PageType` enum):

Table 3. PageType enum

Page type	Renders
SIGN_IN	The initial sign-in (aka login) page
SIGN_UP	The sign-up page (if <code>user registration</code> is enabled).
SIGN_UP_VERIFY	The sign-up verification page (if <code>user registration</code> is enabled; as accessed by link from verification email)
PASSWORD_RESET	The password reset page (if enabled).
HOME	The home page, displaying either the welcome message or dashboard
ABOUT	The about page, accessible from link top-right
ENTITY	Renders a single entity or view model
STANDALONE_COLLECTION	Page rendered after invoking an action that returns a collection of entities

Page type	Renders
VALUE	After invoking an action that returns a value type (though not URLs or Blob/Clobs, as these are handled appropriately automatically).
VOID_RETURN	After invoking an action that is <code>void</code>
ACTION_PROMPT	(No longer used).

The `PageClassList` interface declares which class (subclass of `org.apache.wicket.Page` is used to render for each of these types. For example, Apache Isis' `WicketSignInPage` renders the signin page.

To specify a different page class, create a custom subclass of `PageClassList`:

```
@Singleton
public class MyPageClassList extends PageClassListDefault {
    protected Class<? extends Page> getSignInPageClass() {
        return MySignInPage.class;
    }
}
```

You then need to register your custom `PageClassList`. This is done by adjusting the Guice bindings (part of Apache Isis' bootstrapping) in your custom subclass of `IsisWicketApplication`:

```
public class MyAppApplication extends IsisWicketApplication {
    @Override
    protected Module newIsisWicketModule() {
        final Module isisDefaults = super.newIsisWicketModule();
        final Module myAppOverrides = new AbstractModule() {
            @Override
            protected void configure() {
                ...
                bind(PageClassList.class).to(MyPageClassList.class);
                ...
            }
        };
        return Modules.override(isisDefaults).with(myAppOverrides);
    }
}
```

6.4. Login via Query Args (for Prototyping)

This section describes a (slightly hacky) way of allowing logins using query args, eg `http://localhost:8080/?user=sven&pass=pass`. This might be useful while prototyping or demonstrating a scenario involving multiple different interacting users.

Add the following code to your application's subclass of `IsisWicketApplication`:

```

private final static boolean DEMO_MODE_USING_CREDENTIALS_AS_QUERYARGS = false;

@Override
public Session newSession(final Request request, final Response response) {
    if(!DEMO_MODE_USING_CREDENTIALS_AS_QUERYARGS) {
        return super.newSession(request, response);
    }
    // else demo mode
    final AuthenticatedWebSessionForIsis s = (AuthenticatedWebSessionForIsis)
super.newSession(request, response);
    IRequestParameters requestParameters = request.getRequestParameters();
    final org.apache.wicket.util.string.StringValue user =
requestParameters.getParameterValue("user");
    final org.apache.wicket.util.string.StringValue password =
requestParameters.getParameterValue("pass");
    s.signIn(user.toString(), password.toString());
    return s;
}

@Override
public WebRequest newWebRequest(HttpServletRequest servletRequest, String filterPath)
{
    if(!DEMO_MODE_USING_CREDENTIALS_AS_QUERYARGS) {
        return super.newWebRequest(servletRequest, filterPath);
    }
    // else demo mode
    try {
        String uname = servletRequest.getParameter("user");
        if (uname != null) {
            servletRequest.getSession().invalidate();
        }
    } catch (Exception e) {
    }
    WebRequest request = super.newWebRequest(servletRequest, filterPath);
    return request;
}

```

Rather than using the static `DEMO_MODE_USING_CREDENTIALS_AS_QUERYARGS`, you might also explore using the feature toggle library provided by the (non-ASF) [Isis addons' togglz](#) module.

Chapter 7. Hints and Tips

This chapter provides some solutions for problems we've encountered ourselves or have been raised on the Apache Isis mailing lists.

See also hints-n-tips chapters in the:

- the [Developers' guide](#)
- the [Wicket viewer](#) guide (this chapter)
- the [Restful Objects viewer](#) guide
- the [Datanucleus ObjectStore](#) guide
- the [Security](#) guide
- the [Beyond the Basics](#) guide.

7.1. Per-user Themes

From [this thread](#) on the Apache Isis users mailing list:

- *Is it possible to have each of our resellers (using our Isis application) use there own theme/branding with their own logo and colors? Would this also be possible for the login page, possibly depending on the used host name?*

Yes, you can do this, by installing a custom implementation of the Wicket Bootstrap's [ActiveThemeProvider](#).

The [Isis addons' todoapp](#) (non-ASF) actually [does this](#), storing the info via the [Isis addons' settings module](#) settings modules:

IActiveThemeProvider implementation

```
public class UserSettingsThemeProvider implements ActiveThemeProvider {  
    ...  
    @Override  
    public ITheme getActiveTheme() {  
        if(IsisContext.getSpecificationLoader().isInitialized()) {  
            final String themeName = IsisContext.doInSession(new Callable<String>() {  
                @Override  
                public String call() throws Exception {  
                    final UserSettingsService userSettingsService =  
                        lookupService(UserSettingsService.class);  
                    final UserSetting activeTheme = userSettingsService.find(  
                        IsisContext.getAuthenticationSession().getUserName(),  
                        ACTIVE_THEME);  
                    return activeTheme != null ? activeTheme.valueAsString() : null;  
                }  
            });  
            return themeFor(themeName);  
        }  
    }  
}
```

```

    }
    return new SessionThemeProvider().getActiveTheme();
}
@Override
public void setActiveTheme(final String themeName) {
    IsisContext.doInSession(new Runnable() {
        @Override
        public void run() {
            final String currentUserName =
                IsisContext.getAuthenticationSession().getUserName();
            final UserSettingsServiceRW userSettingsService =
                lookupService(UserSettingsServiceRW.class);
            final UserSettingJdo activeTheme =
                (UserSettingJdo) userSettingsService.find(
                    currentUserName, ACTIVE_THEME);
            if(activeTheme != null) {
                activeTheme.updateAsString(themeName);
            } else {
                userSettingsService.newString(
                    currentUserName, ACTIVE_THEME, "Active Bootstrap theme for
user", themeName);
            }
        }
    });
}
private ITheme themeFor(final String themeName) {
    final ThemeProvider themeProvider = settings.getThemeProvider();
    if(themeName != null) {
        for (final ITheme theme : themeProvider.available()) {
            if (themeName.equals(theme.name()))
                return theme;
        }
    }
    return themeProvider.defaultTheme();
}
...
}

```

and

```
@Override  
protected void init() {  
    super.init();  
  
    final IBootstrapSettings settings = Bootstrap.getSettings();  
    settings.setThemeProvider(new BootswatchThemeProvider(BootswatchTheme.Flatly));  
  
    settings.setActiveThemeProvider(new UserSettingsThemeProvider(settings));  
}
```

7.2. How i18n the Wicket viewer?

From [this thread](#) on the Apache Isis users mailing list:

- *I am trying to internationalize the label descriptions of form actions, eg those in ActionParametersFormPanel. Referencing those via their message id inside a .po file didn't work either. Can this be done?*

The above FAQ was raised against [1.10.0](#). As of [1.11.0](#) (due to [ISIS-1093](#)) it is now possible to internationalize both the Wicket viewer's labels as well as the regular translations of the domain object metadata using the [.po](#) translation files as supported by the [TranslationService](#).

Full details of the [msgIds](#) that must be added to the [translations.po](#) file can be found in [i18n](#) section of the [beyond the basics](#) guide.

In prior releases ([1.10.0](#) and earlier) it was necessary to use [Wicket's internationalization support](#), namely resource bundles. This is still supported (as a fallback):

- create a directory structure inside the webapp resource folder following that pattern [org.apache.isis.viewer.wicket.ui.components.actions](#)
- Inside there create an equivalent [ActionParametersFormPanel_xx_XX.properties](#) or [ActionParametersFormPanel_xx.properties](#) file for the various locales that you want to support (eg [ActionParametersFormPanel_en_UK.properties](#), [ActionParametersFormPanel_en_US.properties](#), [ActionParametersFormPanel_de.properties](#) and so on).

Chapter 8. Appendix: Isis Add-ons (not ASF)

The (non-ASF) [Isis Addons](#) website provides a number of extensions to the Wicket viewer leveraging the APIs described in [Extending the Wicket viewer](#) section, later. While you are free to fork and adapt any of them to your needs, they are also intended for use "out-of-the-box".

At the time of writing the addons available are:

- [Excel](#) component - to export a collection of domain objects as an Excel spreadsheet
 - see also the related [Excel module](#) which can be used to read/import a spreadsheet as an collection of view models or entities
- [Fullcalendar2](#) component - to view a collection of domain objects (with a date) on a full-page calendar
- [Gmap3](#) component - to view a collection of domain objects with a location on a google map
- [\(1.15.0-SNAPSHOT\) pdf.js](#) component - to view a Blob containing a PDF as an image
- [summernote](#) component - to edit a string property using an RTF editor
 - (not yet compatible with [1.15.0-SNAPSHOT](#))
- [wickedcharts](#) component - low-level integration with Highcharts charting library
- [pdf.js](#) component - to view a Blob containing a PDF as an image

Check the [Isis Addons](#) website for the most up-to-date list.

Note that Isis addons, while maintained by Apache Isis committers, are not part of the ASF.
